EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser—Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Abortion, Demography of: United States

Rachel K Jones, Guttmacher Institute, New York, NY, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Abortion is one indicator of undesired fertility. In 2011, there were 1.06 million abortions in the United States, and the abortion rate was 16.9 per 1000 women aged 15–44; one in five pregnancies resulted in abortion. Groups overrepresented among women obtaining abortions and, in turn, having higher abortion rates include: women aged 18–24, black women, cohabiting women, and poor women. Given current abortion rates, it is estimated the 30% of U.S. women will have an abortion by age 45.

Introduction

About half of the 6.6 million pregnancies (including miscarriages) that occurred in the United States in 2008 were unintended (51%). A majority of these pregnancies resulted in unintended births, but 40% ended in abortion (Finer and Zolna, 2014). Thus, abortion is a measure of undesired fertility.

While abortion is one of the most politicized aspects of health care, information on this outcome is essential for several purposes. First, data on abortion are used in the measurement and calculation of the rates of unintended pregnancy (Finer and Zolna, 2014), teenage pregnancy (Kost and Henshaw, 2013), and contraceptive failure rates (Kost et al., 2008). Variations in abortion and abortion rates by characteristics such as age, marital status, and race and ethnicity can suggest groups that have the most difficulties in preventing unintended pregnancy and, in turn, may benefit from targeted public health interventions. This article summarizes the most recent social science and demographic research on abortion in the United States, including abortion incidence, characteristics of women who have abortions, and lifetime incidence of abortion.

Data Sources

The information summarized in this article comes from two national surveys, both conducted by the Guttmacher Institute: the Abortion Provider Census and the Abortion Patient Survey.

The number of abortions performed in the United States, as well as basic information on the availability of abortion services, is obtained from the Guttmacher Institute's Abortion Provider Census, which are periodic surveys of all identifiable U.S. abortion providers. The first of these surveys was conducted in 1974, obtaining data for 1973, the first year in which abortion was legal at the federal level. Since then, the Institute has conducted surveys at variable intervals, up to 5 years apart; estimates are made for years in which data were not collected by interpolation between adjacent years. The most recent Guttmacher provider survey, conducted in 2012 and 2013, collected information on number of abortions performed in 2010 and 2011. More detailed information about the data collection procedures is available elsewhere (Jones and Jerman, 2014).

The abortion incidence data collected by the Guttmacher Institute are considered to be the most comprehensive available (Pazol et al., 2013). While the Centers for Disease Control and Prevention (CDC) collates abortion incidence from state health departments and summarizes this information in an annual report – the most recent CDC Abortion Surveillance Report is for 2010 (Pazol et al., 2013) – the data are incomplete. This is mainly due to the fact that several state health departments, including California, do not collect abortion data; in 2011, California accounted for 17% of the abortions in the United States (Jones and Jerman, 2014).

Information on the characteristics of women who obtain abortion comes from the 2008 Abortion Patient Survey (APS). This survey is the Guttmacher Institute's fourth in a series and uses a design and questionnaire similar to those for the three earlier studies of abortion patients, conducted in 1987, 1994–95, and 2000–01 (Henshaw SK and Kost K 1996; Henshaw and Silverman, 1988; Jones et al., 2002). For the 2008 APS, a random sample of 107 abortion providing facilities – including hospitals, physicians' offices, and clinics – were asked to distribute a 4-page survey to every patient who obtained an abortion during the fielding period (which ranged from 2 to 12 weeks, depending on the facility caseload). The final data set contained information from 9493 women obtaining abortions at 95 facilities. Weights were constructed to correct for any bias produced by deviation from the original sampling plan and nonresponse. In turn, the data are considered to be nationally representative of all abortion patients. To estimate abortion rates by subgroup, information from the 2008 APS was combined with population data from the 2008

Current Population Survey and other national data sources. More detailed information about the study is available in previously published reports (Jones and Kavanaugh, 2011; Jones et al., 2010).

Abortion Incidence and Abortion Rates by Subgroup

In 2011, there were 1.06 million abortions, and the abortion rate was 16.9 per 1000 women aged 15–44 (Jones and Jerman, 2014); put differently, this latter figure means that 1.7% of reproductive aged women had an abortion in 2011. In that year, one in five pregnancies (including births and abortions, but not miscarriages) ended in abortion.

These most recent figures on abortion are more interesting when placed in historical context. The number of legal induced abortions performed annually in the United States increased dramatically in the decade following the legalization of abortion, with the highest number of procedures occurring in the late 1980s, reaching a peak of 1.6 million in 1990 (Table 1). After 1990, even as the U.S. population continued to grow, the number of abortions declined. The incidence of abortion stabilized between 2005 and 2008, but then resumed its long-term decline. The 1.06 million abortions performed in 2011 were the lowest number since 1976. The rate of abortions generally followed the same pattern as abortion numbers with a peak rate of 29.3 abortions per 1000 women aged 15–44 in 1980, to 16.9 abortions per 1000 women in 2011, the lowest since 1973.

While number of abortions and abortion rates are useful national indicators of unwanted fertility, information on the demographic characteristics of women who have abortions, including differences in abortion rates by subgroup, provide a more comprehensive picture.

Public discussions of abortion and the women who have them often focus on adolescents, which may create the impression that most abortion patients are teenagers. However, the majority of women who had abortions in 2008, 58%, were in their 20s; women in their 30s were the second most common age group (22%) (Table 2). Adolescents, or women under the age of 20, accounted for slightly less than one in five abortions (18%). This percentage includes minors, or patients under the age of 18, who accounted for 7% of abortions.

Patterns in abortion rates varied slightly (Table 2). Women in their early 20s had the highest abortion rate, 39.9 per 1000, and the second highest abortion rate was seen among 18–19-year-olds, 34.7 per 1000. Women over the age of 40 had the lowest rate, 3.2 per 1000.

Women's desires to have children, as well as their ability to negotiate the responsibilities of childrearing, may be influenced by relationships with male partners, and abortion varies substantially by union status. Just fewer than half of women having abortions were living with male partners: Married women accounted for 15% of all abortions, and an additional 29% were unmarried, but cohabiting with male partners in the month they became pregnant. Women who were not living with their partners accounted for 56% of all abortions, and most had never been married (45%).

Married women had the lowest abortion rate, 6.6 per 1000, and cohabiting women had the highest, 52.0 per 1000. Never-married women had rates slightly higher than all women, 23.9 per 1000.

Abortion patients are racially and ethnically diverse: non-Hispanic white women comprised 36% of patients, non-Hispanic black women 30%, Hispanic women 25%, and non-Hispanic women of other races for 9%. However, minorities were overrepresented and, in turn, had higher abortion rates. Black women had the highest rate, 40.2 per 1000, followed by Hispanic women, 28.7 per 1000.

In 2008, 16% of women obtaining abortions were foreign-born. This proportion was similar to their representation in the larger population of women and, in turn, the abortion rate

Table 1 Number of reported abortions, abortion rate, and abortion ratio, United States, 1973–2011

[b]Among women aged 20 and older.

for this subgroup was similar to that for all women. Foreign-born women had an abortion rate quite similar to US-born women, 18.8 versus 19.7 per 1000. Notably, 8.0% of all abortion patients were foreign-born Hispanic women, and the abortion rate for this group, 18.4 per 1000, was lower than the abortion rate for all Hispanic women.

Education can influence fertility intentions in several ways. For young women in particular, the desire to pursue or complete education can provide motivation to delay childbearing, and both attendance and completion of schooling can provide access to information and resources (e.g., sex education, health care) that better allow them to avoid unintended pregnancies. The overwhelming majority of abortion patients aged 20 and older, 88%, had graduated from high school. Most commonly, 40% had some college or an associate's degree, and one in five women had a bachelor's degree or higher.

One common reason women report terminating unintended pregnancies is that having a baby would prevent them from achieving goals such as pursuing an education. Patterns in abortion rates by educational attainment may be due, in part, to educational goals. For example, the higher abortion rate

among women with some college (24 per 1000) may reflect the fact that this population is currently in school and having a baby would prevent them from achieving their goal. The substantially lower rate among women with college degrees (12 per 1000) may reflect that higher education provides exposure to information about and access to contraception, and, perhaps, increased motivation to avoid unintended pregnancy in the form of job and career opportunities.

Abortion and motherhood are often regarded as opposing interests, and it is sometimes assumed that women who obtain abortions do not want to be mothers because they are unable or unwilling to assume the responsibilities of raising a child. But the majority of women obtaining abortions in 2008, 61%, already had children, including 34% who had two or more. Women with only one prior birth had an abortion rate almost twice as high as women with no children and those with more than one prior birth (29.6 versus 17.4 and 17.5 per 1000, respectively).

A substantial minority of women obtaining abortions in 2008, 42%, reported incomes that qualified them as poor, and an additional 27% were low-income, having family incomes between 100% and 199% of the federal poverty line. Poor women were overrepresented among abortion patients and had one of the highest abortion rates of all the subgroups examined, 52.2 abortions per 1000. As income levels increased, the abortion rate decreased, and women with family incomes at or above 200% of the federal poverty level had a rate slightly lower than half of the national rate at 9.3 per 1000.

Almost three-quarters of women obtaining abortions in 2008 reported a religious affiliation, most commonly Protestant (37%). Catholic was the second most common affiliation (28%) and a similar proportion of abortion patients, 27%, indicated they had no religious affiliation. One in five abortion patients identified themselves as born-again, evangelical, charismatic, or fundamentalist, 75% of whom were Protestant (not shown).

Protestants and women reporting 'other' as their religious affiliation had the lowest abortion rates of the affiliations examined, 12.7 per 1000. Born-again/fundamentalist Protestants had an abortion rate almost half as low as all women, 11.4 per 1000 (not shown). Women with no religious affiliation had a higher abortion rate than those with any affiliation, 32.2 per 1000. Catholics had an abortion rate slightly higher than the national rate.

Lifetime Incidence of Abortion

Data from the 2008 APS were used to determine the lifetime incidence of abortion, based on the proportion of women in each age group who were obtaining first abortions. The cumulative first-abortion rate, or proportion of women estimated to have had an abortion by the time they reach the end of a specified age range, was obtained by multiplying each age-specific first-abortion rate by the number of years in that age group (e.g., 15–17 age group had a multiplier of three), and summing all age groups up to that age group. The lifetime incidence of abortion is the equivalent of the cumulative first-abortion rate for women aged 40–44.

Table 3 Abortion rate, % first abortions, first-abortion rate and cumulative first-abortion rate, 2008

	2008				
		% Obtaining first abortion			
Age at outcome	Abortions per 1000	95% CI		First-abortion rate	Cumulative first-abortion rate
<15[a]	2.4	97.3	83.4–99.6	2.4	2.4
15–17	11.3	85.7	81.6–89.0	9.7	31.5
18–19	34.7	73.4	69.6–76.8	25.5	82.5
20–24	39.9	55.6	53.2–57.9	22.2	193.4
25–29	28.6	39.9	36.8–43.1	11.4	250.5
30–34	17.1	34.6	31.2–38.1	5.9	280.0
35–39	9.5	32.2	28.6–36.1	3.1	295.3
≥40[b]	3.2	34.5	28.5–41.2	1.1	300.9
Total	19.6	50.4	48.2–52.6	9.9	300.9

[a]Denominator is women aged 14.
[b]Denominator is women aged 40–44.

In 2008, there were 2.4 abortions for every 1000 adolescents under the age of 15 (Table 3). Because 97% of these were first-time procedures, the first-abortion rate and cumulative first-abortion rate for this group were also 2.4 per 1000. The overwhelming majority, 86%, of adolescents aged 15–17 were obtaining their first abortion. In turn, the first-abortion rate for this group was slightly lower than their overall abortion rate (10 vs 11 per 1000). By adding the first-abortion rate for women <15 to 3 times the first-abortion rate of women 15–17 (to account for the 3-year size of that age group), their cumulative first-abortion rate was 31.5 per 1000.

The cumulative first-abortion rate increases with age, and women aged 40 and older had a rate of 301 per 1000 women. Put differently, an estimated 30.1% of women aged 15–44 in 2008 will have an abortion by age 45 if exposed to prevailing abortion rates throughout their reproductive lives. Similarly, an estimated 8% of U.S. women would have had an abortion by age 20% and 25% by age 30.

A Note About (Potential) Change

Information on abortion patients collected in 2008 is the most recent available. The abortion rate declined somewhat substantially (13%) between 2008 and 2011 (Jones and Jerman, 2014) and may have increased, further decreased or stabilized since that time. However, it is unlikely that the general patterns in the characteristics of women who obtain abortions changed as dramatically since 2008. Research examining changes in characteristics of women who had abortions between 1974 and 2004 did find substantial demographic shifts – for example, the proportion of abortion patients under the age of 20 dropped by almost half (from 33% to 17%), and the proportion aged 30 and older increased – but, these changes occurred gradually over the three decades; moreover, these 'demographic transitions' occurred even while the abortion incidence was increasing and decreasing (Henshaw and Kost, 2008). Thus it is likely still the case that the majority of abortion patients are in their 20s, that most women having abortions have one or more children, are unmarried, and have some college education; similarly, while

the actual abortion rates for various subgroup may have changed, the patterns in rates are likely similar (e.g., women aged 20–24 probably still have the highest rate compared to women in other age groups).

The one characteristic that has the potential to change somewhat more rapidly is poverty. Between 2000 and 2008, the proportion of abortion patients living below the federal poverty level increased 59%, from 27% to 42% (Jones and Kavanaugh, 2011; Jones et al., 2010). Similarly, the abortion rate for this group increased 18% even while it decreased for the larger population (Jones and Kavanaugh, 2011). To some extent, this was due to the fact that 2008 was in the midst of the economic recession, and there were more poor women in the population (Jones et al., 2010). Still, poor and low-income women have been overrepresented among abortion patients for as long as it has been measured on the APS and this general pattern is likely to remain unchanged.

Similarly, the lifetime incidence of abortion is directly influenced by the abortion rate. Since this declined between 2008 and 2011, it is possible that the lifetime incidence has declined as well.

Conclusion

Abortion is an important measure of unwanted fertility. Some 40% of U.S. unintended pregnancies end in abortion as do 21% of all pregnancies (Finer and Zolna, 2014).

Abortion has largely been declining since the early 1990s, but research has yet to uncover the causal factors behind this trend. The decline is likely due to a variety of factors including increased access to highly effective contraceptive methods, inability of women to access abortion services (and a concomitant increase in unintended births during some parts of the country), and fewer women becoming pregnant (Jones and Jerman, 2014).

Disparities in rates of abortion among different groups of women often reflect vulnerabilities in other aspects of life, including poverty, insurance coverage, access to health care as well as other types of social and economic disadvantage. These conditions can pose structural, logistical, and personal barriers that make it difficult for disadvantaged groups of women to access and effectively use contraception and plan their pregnancies compared to more socioeconomically advantaged women.

Despite recent declines, it is worth noting that the abortion rate in the United States is generally higher than those of Western and Northern European countries. In 2008, abortion rates were substantially lower in Switzerland (7 abortions per 1000 women), Germany (7), the Netherlands (8), and Finland (11) relative to the United States (19) (Sedgh et al., 2011). These comparisons suggest that there is room for improvement to helping U.S. women avoid unintended pregnancies.

This article is a revision of the previous article by R. Vierhaus, volume 1, pp. 5–9, © 2001, Elsevier Ltd.

Abstract

This article focuses on the highly contested but widely employed historiographical category 'absolutism.' It illustrates the origins of the term and provides an account of its main scholarly interpretations. Together with showing how divided academic opinions are with regard to the meaning(s) of 'absolutism,' the following pages ask whether it is the same thing to speak of absolutism with regard to the practices of early modern European monarchies or with reference to the political ideas of so-called absolutist theorists. In so doing, this article provides a comprehensive account of debates on absolutism and, at the same time, suggests that further work needs to be carried out on its theoretical aspects. In this respect, particular attention is directed to a series of key principles, which are meant to encapsulate the core of an early modern doctrine of absolutist monarchical sovereignty. This will help to delineate the history of absolutism (term, practice, and concept) in its multifarious political aspects and its rich theoretical dynamics.

Absolutism and Its Historiography

All categories ending with the suffix *'ism'* are problematic and often generate endless historiographical debates. This could not be more true than in the case of 'absolutism.' Like a great number of *'ism'* terms, absolutism is of nineteenth century coinage (Höpfl, 1983; Cuttica, 2013). Prior to 1770 'absolutism' in English, German, and French did not exist, but 'absolute monarchy,' '*monarchia absoluta*,' '*pouvoir absolu*' did (Schmale, 1998). This gap between the concept and the thing has caused vibrant – if not vehement – controversies amongst historians. Thus, for the French scholar Georges Durand absolutism is "that empty word into which everyone reads the meaning he wants, that favorite cliché of historians in a hurry" (Durand, 1976). On the other side of the Channel, Nicholas Henshall maintained that the concept of absolutism originated with the French Revolution whose goal was to condemn everything associated with the *ancien régime*. Therefore, to use it corresponds "to accept the propaganda of revolutionaries as historical reality." On the same plane as 'renaissance' and 'enlightenment,' absolutism is employed by historians to mean 'whatever' they 'want it to mean,' so that it turns out to be "an impressive excuse for sloppy thinking" (Henshall, 1992).

Leaving aside this highly polemical vein, we can plausibly argue that the study of absolutism – whose literature is immense – has been informed by three major perspectives. These are the conservative perspective for which it has always existed; the Marxist perspective for which it was an epoch between feudalism and capitalism, contaminated by and connected to both; and the revisionist perspective for which there was no absolutism and, therefore, we should not speak of it. Besides these three consolidated schools, more recently historians have taken positions which can be divided into two broad camps: those who reject the notion of absolutism per se and regard it in terms of social collaboration (between a dependent king and an increasingly powerful and influential nobility) and those who have contested the former approach. Amongst the first can be cited William Beik, Sir George Clark, James B. Collins, Sharon Kettering, Roger Mettam, Julian Swann, Peter Wilson, and Hillay Zmora. As for the second group, John Brewer, Michael J. Braddick, Daryl Dee, Brian M. Downing, Philip Gorski, John J. Hurt, and John A. Lynn can be mentioned (Cuttica and Burgess, 2012).

One important feature of these interpretations is their prevalent focus on the analysis of politics, diplomacy, dynastic structures, and court culture. Absolutism has been studied in its practical (legislative, executive, administrative) dynamics, that is, as an increasingly dominant political, fiscal, bureaucratic, and military entity from the sixteenth to the late eighteenth century in Europe. At a theoretical level, the attempt to define the pivots of absolutist political thought has been combined – not always successfully – with the examination of the relationship between the theories and the diversity of historical arguments, as well as of the interplay between the languages of absolutist theory and the realities of social experience and political practice. Taking Jean Bodin's *Les Six Livres de la République* (1576), and earlier the reworking of Roman law pursued by some French lawyers (Church, 1941) as the foundational moment in the mature development of a theory of absolutism, it has been argued that the latter can be found when "the ruler in any State holds sovereign authority, cannot be actively resisted, can change existing constitutional arrangements in a case of necessity (though he ought otherwise to maintain them), and should be obeyed by his subjects provided that his commands are not contrary to those of God and nature" (Sommerville, 1999; Russell Major, 1994).

Distinguished (more or less plausibly) both from republican polities (e.g., The Netherlands, Venice, the Swiss cantons) and despotic States (e.g., Turkey, Muscovy) at one stage or another throughout the long early modern period (*c.* 1500–1800), absolutism was considered to be the system of government of countries such as Spain, France, England, Denmark, and the Habsburg territories. This seemingly clear picture, however, has not found much agreement within the scholarly mainstream, where not only the practices, but also the principles of the absolutist State are disputed. Whereas Herbert H. Rowen skeptically stated that "absolutism was historically defined to fit the case of Louis XIV" (Rowen, 1969), Roland

Mousnier had no doubt that absolutism existed and concerned both monarchies and other forms of government, being "sovereignty which recognized no superior" (Mousnier, 1971). On his part, François Olivier-Martin singled out four types of *puissance absolue* as articulated by French monarchists since medieval times: the king as defender of the public good against private interests; the king as feudal *suzerain des suzerains* (highest overlord); the king as *Roy Très Chrétien* (protector of the faith); the king as emperor in his realm (Olivier-Martin, 1988). Jean Mesnard maintained that the seventeenth century did not invent the 'divine right monarchy' in that it continued a centuries-old legacy. Its feature was thus the development of absolute monarchy with a clear prominence of profane elements, even though religious language persisted in the description of power (Mesnard, 1996). And if for David Parker "absolutism was always in the making, but never made," and was "no more than a conservative philosophy" aimed at affirming royal authority in a world confronted by rapid change (Parker, 1983), Fanny Cosandey and Robet Descimon acknowledged that absolute monarchy constituted "a vast discourse endowed with historical effectiveness" (Cosandey and Descimon, 2002). Such a discursive mode did not simply convey the idea of a display of authority, but it enunciated a proper system of government. Etienne Thuau distinguished between a philosophy of monarchy (theorists and lawyers) and a religion of monarchy (parties, ceremonies etc.) (Thuau, 1966). Famously, Marc Bloch viewed absolutism as a sort of religion. The prince embodied a lay part and a religious one too: the image of priest and of king coexisted. Likewise, the monarch was commonly represented as *Roi-thaumaturge* (Bloch, 1924).

Another historical trait of absolutism was the tension between the personalization of kingship – whereby the sovereign was depicted as the individual who was superior because of his qualities and, therefore, one who had to be obeyed and adored; and a process of abstraction of kingship where he was associated with the purity and public presence of the State (Keohane, 1980). Although "[t]here was a vast gap between such claims [to kingly absolute power] and political reality," for Henry Kamen the theory "helped to justify subsequent efforts by princes to free themselves from the control not only of their elites but also, most importantly, of the Church and papacy, which had also made far-reaching claims to political authority." *De facto*, 'absolutism' was "an ideal construction, in which thinkers attempted to create order out of the disorder they saw around them": this means that "the theories are a significant attempt to deal with a real problem" (Kamen, 2000). On his part, Helmut G. Koenigsberger thought that "[t]he growth of absolutism […] could be furthered either by the secularization of church property where the Reformation was introduced or by an effective alliance with the old church where it was rejected" (Koenigsberger, 1978).

While such a range of divergent interpretations might leave readers daunted, it should nonetheless make them aware that to study absolutism entails a complex and nuanced analysis of the experiences of absolute power across different geographical and cultural areas of early modern Europe. This warns the reader to be suspicious of conventional views based on an evolutionary model, whereby from a paternal monarchy, absolutism was deemed to have moved on to a 'divine right' monarchy and, subsequently, to a rational and national State. In fact, absolutist parlance and politics were partly products of Renaissance, Baroque, Catholic, and Protestant thinking; they were also part and parcel of the new philosophical and scientific trends, and as such, they may be considered to have actively contributed to the emergence of the loosely defined 'modern world.' Despite the continuity of certain ideas and policies throughout time and across places – be it sufficient to refer to the *absolutist* regimes of Charles I of England, Philip II of Spain, Louis XIV of France, the Russian Tsars, Christian V of Denmark, Charles XII of Sweden, and some small States in the Italian peninsula – the patterns of change were composite and multistranded.

Absolutism in Practice and Theory

Departing from the conviction that absolutism is "an essentially negative term" which explains more about what it *was not* than about what it *was* (Bonney, 1987), it is pivotal to establish a little more clearly what absolutism means and what it is; what thinkers thought absolute power was and what they meant by it. To do this, we need to tease out the presence and status of some relevant and recurrent features of the practice (the acting out) as well as the theory (the arguing out) of absolutism. Although the analysis of early modern absolutism, here undertaken, focuses on the ideal descriptions of how a government should function rather than on how it actually worked, a few words on what factors can be considered as central to any absolutist policy are in order. Amongst the latter are the role of centralization of authority; the creation of a bureaucratic apparatus; the monocratic nature of power; the elaborate ceremonials centered on the sacredness of power (e.g., the *sacre*, the *lit de justice*, funerals); the place of the army and that of the fiscal structure; the influence of the court; the role of diplomacy and dynasty; the function of the theater, the arts, ballet, court festivals, masques, and architecture in the consolidation of power (the theatricality of power and the power of sight); the role of secularization as much as that of religion in the development and expansion of absolute monarchies. Besides, political absolutism was transconfessional in that both Catholics and Protestants (of various denominations) embraced it.

As for theory, absolutist thinkers subscribed to *some* (not indiscriminately to all) of the following principles as well as concepts: the absolute and indivisible power of monarchs; the unconditional obedience of subjects; the advancement of the power of the king (his will) versus the ancient and immemorial liberties, rights of Parliament and privileges of assemblies; a strong criticism of democracy (the people could not govern because they represented an irrational and headless multitude, so that popular government was the worst polity); the rejection of natural rights theories and the idea of the natural freedom of mankind; the derivation of power from God whereby the king was responsible for his decisions and actions to Him only; the formulation of monarchy as the best of all governments, the most perfect and natural (oneness to be found in Nature); notions of monarchical sovereignty as inalienable, hereditary, and not elective, mixed, or limited. Moreover, it was

traditionally stated that the absolute king held for himself some important powers: to make laws without the aid of any intermediate body; to condemn to death and regulate life; to wage war and stipulate peace; to coin money; to appoint ministers and magistrates; to levy taxes and impositions. The king was also often reputed to be above the law. His grace granted the estates or the Parliament the right to propose new legislation or present grievances. His will was infallible, and he could not be held accountable for his deeds to the will of the community, artificially mediated through customary or fundamental laws. The ruler's wisdom and rationality were universal. Therefore, his actions inevitably conformed to ideals of divine and natural justice. In taking decisions, he was protected by the medieval doctrine of the mysteries of State, which pertained exclusively to him as his own business in which subjects or counseling bodies could not meddle (Kantorowicz, 1957; Méchoulan, 1985). Some of these ideas were seized by a series of phrases to which authors frequently resorted to describe the absoluteness of the king's legislative power (*legibus solutus*, *lex loquens*, *quod principi placuit legis habet vigorem*) and his authority (*majestas absoluta*, *summa potestas*, *potestas perpetua*, *potestas legibus soluta*, *nam regia maiestas non moritur*). The king was both the voice and the eye of the kingdom.

Other pivotal traits of the absolutist framework were that: power stemmed from God; the Bible, nature, and history confirmed its divine origin (this frequently generated contrast between monarchies' pretences to absolute power and the Church's); the form of government could not be subject to discussion because it was a monarchy where power was transmitted from the incumbent ruler to the (in some cases strictly male) heir via primogeniture; in contrast to tyrants, kings – fathers and shepherds of their people – were regarded to be in tune with God's commandments; monarchical tyranny was better than anarchy. To these can be added the identification of the king with the monarchy, the State, and the *patria* (fatherland). Indeed, from the late sixteenth century, in countries like England and France, the sovereign became to be portrayed as *patria ipsa*. The king was not only superior, but he was immortal (not his body – *persona personalis*, but his dignity – *persona idealis*).

Making use of biblical teachings, classical models, history, analogical reasoning, Roman law, the fathers of the Church, and modern authors alike, absolutist discourse addressed both the issue of the origins of government and that of the method of government (governance). So, absolutists like Pierre de Belloy, Jean Bédé de la Gourmandiere, François Le Jay, John Cowell, Sir Robert Filmer, Claudius Salmasius, and Thomas Hobbes (Cuttica, 2011) underscored the idea that power was strictly the affair of few people. Accordingly, in many cases they couched their works in the language of the theory of order (where the hierarchical element was predominant); employed the notion of kingly 'absolute' power in the sense of the ruler being both supreme (*legibus solutus*) in his command over Parliament and subjects, and independent from an allegedly superior authority (Pope or Emperor); and resorted to the tenet that the will of the monarch ruled because he was the sole source of power (e.g., Filmer, 1991).

The affirmation of these principles during the seventeenth century signaled a transformation in absolutist reflection. This is to say that theorists depicted the king as the protector of the nation. For this reason, the parliamentary principle that the king was bound to respect the law of the land was rejected since he *was* the speaking law of the land. By making the king the exclusive interpreter of the law, absolute monarchists also dismissed the role of lawyers and jurisconsults. Privileging the political standpoint to the detriment of the legalistic one, they claimed that the absolute king was the only creator of legislation in the kingdom. This explains how some of the political conflicts of the late sixteenth and early seventeenth centuries centered on the question of who was the ultimate holder of the *interpretatio* of the law. Opting for the *interpretatio politica*, absolutists adhered to the concept that the king was totally self-sufficient in ruling the country and that no further legal aid was necessary.

Moreover, if some thinkers (e.g., King James VI and I Stuart) occasionally maintained that monarchs were limited by laws and institutions to which they, or their predecessors, had consented and submitted, others like Filmer and Hobbes whose *Leviathan* (1651) is considered to be the highest and most sophisticated articulation of absolutist doctrine – defended the voluntaristic approach to the law-making process on the basis of which the will of the sovereign had the utmost preeminence in the body politic. They insisted that the king's singleness of will gave order, unity, control, and shaped an unformed and heterogeneous mass (the body politic). Thus, the monarch wielded uncompromising power; was complete in his solitude; had a clear identity; could not be mistaken thanks to the hereditary principle (uncertainty being the faulty outcome of people's ignorance); and was perfect in his majesty and superiority. Likewise, his law had to be unconditional; clear, precise, established, and certain; flawless (Cuttica, 2012). Some seventeenth-century authors went so far as to claim that the king was justified in acting arbitrarily by the necessity to bypass the law when it was too rigid and the safety of the State was at stake. With regard to the monarch's political conduct, the notion of arbitrary power stressed the importance of values such as courage and wisdom. In some cases, this led thinkers to advocate the need to resort to violence to protect the State and the common good (e.g., Guez de Balzac, 1631; Cardin Le Bret, 1632).

These ideas glorifying the majesty of kingship derived from Roman civil law writers of the first half of the sixteenth century, especially in France. Their goal was to place the monarch above all his subjects in a way "resembling a *potestas legibus soluta* in action" (Church, 1941). Many theorists appropriated the third-century jurist Ulpian's formulae *rex solutus legibus est* and *quod principi placuit legis habet vigorem* to define "the monopoly the king exerts over the law" (Daly, 1978). Moreover, the king was considered as 'lex animata' – the breath which regulated the legislative life of the kingdom, and without whose intervention the body politic could not survive. Thus, *potestas absoluta* corresponded to various functions the monarch possessed: suspending, derogating, pardoning, mitigating, and facing unforeseen circumstances. It was a form of 'discretionary power' which shaped the concept of royal prerogative. These principles greatly emphasized the role of the king as national monarch capable of guaranteeing the making of the law and its preservation. To put political thinking on this track were *politiques* such as Jean Bodin, Etienne Pasquier, Pierre de Belloy,

Louis Servin, William Barclay, Pierre Pithou, Guy Coquille, and Christofle de Thou, whose works proved largely influential across Europe. In particular, they shaped the ideas and the policies based on the 'reason of State' paradigm, which Cardinal Richelieu and his supporters employed in the seventeenth century (Cosandey and Descimon, 2002; Church, 1941).

According to the historian Jean-François Courtine, the 'absolutisation' of power in the *État Baroque* also occurred through "a resacralisation of the State ['État']." It was thus a 'crypto-theological' element in the political ideas of the early seventeenth century that conveyed concepts of sovereignty and models of State-practice. In fact, the power of the State and the features theorists attributed to it, derived from papal power and the principles associated with it, especially the concept of pontifical *plentitudo potestatis*. The sovereign appeared as a superior human type. In practice, it was the process of 'sacralisation' and 'deification' that led to the 'self-governance' and 'rationalization' of political monarchy. It followed that the Church was an absolute and rational monarchy founded on a mystical basis, while the State was a mystical monarchy founded on a rational basis (Courtine, 1985). However, it is essential to remember that not all thinkers expounded an idea of the sacralised image of the king. In fact, absolutists often presented the sovereign as an efficient, patriotic, and rational ruler at a time of both internal and external tension. For Joël Cornette the king was a plurality of things. He embodied a series of roles: "overlord, lawmaker, judge, warrior, demigod, healer, minter and obedience-supplier through levies." The État Baroque was the response to a society that was anxious and unstable. It represented the moment when the scientific revolution and the modern prince met to engender a new spirit that opposed traditional ways of thinking and proposed new shared values at the center of which stood reason. This phase corresponded to the creation of an *État*-Leviathan whose pivots were order, authority, and profit (Cornette, 1985).

This model of government served as spearhead with which to attack republican institutions seen as entities that fortified the private interests and individual passions of a minority of powerful nobles. In contrast to eighteenth-century philosophers like Montesquieu, absolutist theorists argued that republics represented a deleterious mixture of aristocratic factionalism and democratic aspirations. On the contrary, the pursuit of the *bien publique* could only be guaranteed in an absolute polity. Linking patriotism and rationality as cornerstones of monarchical government, absolutists reacted to Montesquieu's well-known claim that only republics prompted people to embrace civic virtue and patriotic feelings. They contended that a new 'decision-making' monarchy assured prosperity and safety (*Polizey*) through a very empirical approach to problems in the polity. This 'public safety'-based structure was founded on a balance of forces where the estates were replaced by the individual citizen, and economic rationality was 'accompanied' by 'moral improvement.' This gave a novel – more modern – face to monarchy. Such a situation created the mutual collaboration of an enlightened State-apparatus guaranteeing 'convenience and safety' with an 'enlightened citizenry' patriotically engaged in abiding by the laws and loyal to the government representing the fatherland (Kontler, 2012). In summary, political, theological, metaphysical, and temporal aspects all contributed to define the history of absolutism and to establish the administrative, fiscal, and military form of the modern State.

Besides all of the aforementioned characteristics, to investigate the nature of absolutism in historical perspective means to take into further account the significant changes that occurred in European societies and their political structures during the eighteenth century. In other words, it is important to follow – although not teleologically – the trajectory of both practice and theory from medieval England to eighteenth-century Prussia through Enlightenment France and Naples, and from the vocabulary of indivisible, inalienable, hereditary sovereignty to descriptions of the monarch as the constitutional artisan of a complex administrative apparatus. Hence absolutism and monarchical discourse need to be read in relation to republicanism (especially, its conflict with it); enlightened despotism; patriarchalism; patriotism; liberty (e.g., intellectual liberty and freedom of opinion); property (protection of subjects' property); the state of nature; scientific developments; toleration; iconographic propaganda; and the ethical sphere (both public and private). The advent of the eighteenth century forced absolutists to confront new factors informing *the art of politics*: cameralism, publicity, political secularisation, attention to the civil freedoms of citizens, the politicization of sculpture (as was the case, for instance, under Empress Catherine II of Russia), the new utilitarian spirit. A different era had dawned and with it different ways of conceiving (absolute) power.

Absolutism: Terminology and Typology

It has been observed that three groups of meanings were attached to the term 'absolute': uncompromising, unconditional, complete; positive, certain, decided; faultless, perfect (Daly, 1978). As a result, it seems plausible to identify – at least – seven theoretical cornerstones enabling a configuration of political absolutism that concerns the ruler:

- Ab-soluteness (absolved and above)
- Independence (internal and external)
- Solitude
- Perpetuity
- Exclusive inequality (of the sovereign compared to the equality of the rest of the subjects)
- Individuality
- Effectiveness

This configuration of absolute power helps to separate absolute government from tyranny in that the latter was marred by cruelty and by the search for private interest, while the former aimed at the pursuit of the public good. Tyranny acted in a vacuum (legal, ethical, hereditary), whereas the absolute king intervened in the juridical sphere with his supreme power, in order to mitigate the rigidity of the law and avoid injustice. Although it is often claimed that the degree of absoluteness of a king's power depended on the extent to which the law of nature was thought to legislate, this does not mean that he was held to be limited. In fact, absolutists, of the kind described here, regarded monarchs as capable of restricting the domain of

political life that the law of nature could regulate. Consequently, not only laws but also customs were the outcome of the supreme decision of the *lex loquens* king, who was depicted as the creator of the nation's ethos. This implies paying attention to the following units of meanings as foundations of absolute rulership: arbitration, choice, judgment, decision, will, mastery, and authority.

On the whole, any analysis of absolutism needs to examine what theorists wrote and described, as well as the concepts they expressed in a prescriptive and normative way, according to their theoretical, ideological, and doctrinal objectives. Reality might not have necessarily corresponded to their designs, but what is interesting is precisely the nature of these designs, projects, visions of political society and government, power and authority, sovereignty, and liberty. More focus should be on the conceptual sphere, especially in relation to the idea of sovereignty and, within it, to the modality(ies) of power. In other words, it is necessary to investigate how ideas formed; how they served to think or reshape institutions, polities, and systems of government; how intellectual categories helped communities to reflect on their organization and their life; how concepts legitimized actions; how they gave meanings as well as significance to different narratives of the past. Absolutism should thus be approached as *words in action*. It should also be read as part of humanist philosophy in that it is placed at the center of its reflection, man with his rationality and will.

The foregoing points enable us to identify a series of paradigms – interdependent and mobile rather than fixed and a-contextual ones – that characterize the history of European absolutism. These different strands help not only to comprehend the role of ideas in the practice of absolute policies, but they also show the weight of certain thinkers in their transnational dimension. As a result, a sample of what are the most relevant and – it need be repeated – historically overlapping, nonmutually exclusive but interchangeably connected political, ethical, and intellectual models informing absolutism can be provided:

1. Machiavellian absolutism (Tacitean) >> insistence on prudence and the tradition of the mirror of princes (religion as an instrument in the hands of those in power);
2. Bodinian absolutism >> emphasis on the indivisibility and inalienability of sovereignty, but also on the role of positive laws and property;
3. Patriarchalist absolutism >> Filmer and the Adamite paradigm (family-model; ruler as the founder and shaper of the commonweal's ethos, its customs, and laws);
4. Patriotic absolutism >> French monarchists against Jesuit and Ultramontanist ideas; monarchist discourse in eighteenth-century Denmark and Prussia;
5. Constitutional absolutism (royalism) >> the specific case of seventeenth-century England;
6. Reason of State absolutism >> priority given to the *arcana imperii*;
7. Divine absolutism >> focus on the divine right theory (references to witchcraft and mystical authority). Divine rights of kings primarily concerned obedience;
8. Hobbesian absolutism (*Leviathan*) >> role of the state of nature and totalization of politics;
9. Miraculous absolutism >> royal touch and insistence on the king's physical and moral characteristics (king seen not only as God, saint, and giver of justice, but also as wizard).

These models operate as analytical templates through which to explore and decipher the nature of absolutism in early modern Europe. They present the latter as an intellectual and practical intercourse made of different (at times contrasting) languages, vocabularies, paradigms, functions, and dynamics. They help to go beyond the interpretative impasse whereby absolutism is inevitably the expression of static, archaic, and oppressive political societies. They also prompt to revise two other common assumptions about absolutism: that it was a myth and that it was founded exclusively on the idea of the sacred and the dimension of the divine. Likewise, they do not look to absolutism exclusively as an "ahistorical phenomenon connected with the aggrandizement and the centralization of the state." Instead of proposing an ahistorical image of absolutism as "a strange and dangerous beast" aspiring "to rise above reality" (Kossmann, 1976), they bring back into play the various languages that theorists deployed in disputes and, at the same time, cast light on traditionally antagonistic readings of absolutism as either feudal, bourgeois, or fiscal.

Thus, if we subscribe to the prescription that for the historian to make a legitimate use of an 'ism' it is necessary to have people deriving ideas and finding in a thinker "an authoritative expositor" of views they agreed with and shared (Höpfl, 1983), then absolutism (as we have used it in this article) is plausibly employed. In fact, we have described a core of political, juridical, and doctrinal principles adopted by early modern theorists to portray specific images of kingship as well as to respond to rival visions of the body politic in debates across Europe. In addition to connecting absolutism to historical and social phenomena, this article has also depicted it as the embodiment of particular political traditions, theoretical languages, and rhetorical tropes. In this respect, absolut*ism* needs to be approached as a network of meanings and practices that shaped the history of early modern Europe.

Conclusion

There are two more aspects of the history of absolutism that are worth mentioning. First, it is important to underscore that both as practice and as doctrine, absolutism took different shapes in different contexts at different times. Despite all the common elements highlighted above, it is historically essential to be aware of the contextual varieties surrounding the phenomenon and its ideas. Second, it has to be remembered that there exists a series of concepts which have recurrently (but often wrongly) been associated with absolutism. Amongst these the main ones are: dictatorship, caesarism, autocracy, despotism, and totalitarianism. A few words are in order with regard to the last two. As for despotism, some authors considered it a legal form of government, implying the servile nature of a people where the relation between governor and governed was like that between a master and his servants/slaves. Therefore, it was generally associated with so-called barbarian peoples (Asiatic populations). In the eighteenth century, philosophers such as Boulanger, Helvétius, the physiocracts, Mably, and Rousseau

viewed despotism as the death of the body politic, while Benjamin Constant spoke of 'despotisme de la liberté.'

As for totalitarianism, we need not confuse it with absolutism in that the former is quintessentially a twentieth-century phenomenon (e.g., Nazism, Fascism, Stalinism) corresponding to the total identification of each individual with the whole State. Totalitarianism entails the politicization of life, and of every dimension of it. For Hannah Arendt, it implies the alienation of private existence and the transformation of human nature. An ideology of terror and the encompassing role of propaganda are central factors in the construction of a totalitarian polity. Likewise, a one-party-only structure and the systematic deployment of a brutal police force are pivotal to its functioning. The identification of the enemy, of the often-fictitious 'foe,' represents another crucial trait of this form of authoritarian regime. Given that the use of technology and a general control over the economic sphere inform it, its workings become a pervading threat within society (Arendt, 1951). Totalitarianism asks people not only for their active political support, but their full participation in the life of the State, so that their pastimes are invested too. This explains the presence of an oppressive apparatus of constant surveillance of the private existence and space of the citizens/subjects. The process of industrialization and the related concept of the masses are also considered key aspects of the totalitarian State (Friedrich and Brzezinski, 1956).

It is widely accepted that the nineteenth century with the gradual emergence of democracy, constitutional change, and national awakening in many European countries, as well as the forging of new political ideas/ideals, put an end to absolutism in its more traditional mold. However, any attempt to pursue a much-invoked "reassessment of absolutism" (Bonney, 1987) cannot overlook the fact that contemporary sociologists and politologists speak of 'neo-absolutism,' which in contrast to centralized absolutism, is "post-modern and polycentric, dissipative [dispersed, scattered], omnipresent and yet dislocated. It has too many centres, almost all of which are invisible. It is in the net with innumerable ramifications. Therefore, it becomes "elusive" (and, maybe, even impregnable)" (Revelli, 2010).

If anything, these considerations confirm that absolutism is more than a complex historiographical category. They show that it continues to be a historically fascinating and conceptually rich object of study across multiple disciplines. It can thus be said that the interesting history of absolutism is not over yet.

Abstract

A firm's competitive advantage originates increasingly from absorbing external knowledge. Absorbing external knowledge and the underlying learning processes are referred to as a company's *absorptive capacity*. In this article, we outline research trends on absorptive capacity. We apply a bibliometric analysis to describe the concept's historical development, define the intellectual core of the absorptive capacity concept, and discuss recent conceptualizations. Then, we identify two prominent streams in the absorptive capacity literature and provide a new approach on how to integrate them. Finally, we provide an outlook on possible themes in future research on absorptive capacity.

Introduction

Both practitioners and academics increasingly recognize that competitive advantages no longer rely on internal knowledge alone, but rather originate from absorbing external knowledge. This in turn is based on learning processes, which are directed at exploring, assimilating, transforming, and exploiting external knowledge (Camisón and Forés, 2010; Gebauer et al., 2012; Lane et al., 2006). These learning processes support companies in converting their external knowledge into innovations. The literature refers to the absorption of external knowledge and the underlying learning processes as a company's *absorptive capacity* (Cohen and Levinthal, 1989, 1990).

Absorptive capacity, as an application of external knowledge for commercial purposes, can lead not only to product or service innovation but also to strategic innovation. Strategic innovation aims at reshaping the existing business model, opening up new and uncontested markets, and creating a leap in customer value (Christensen et al., 2002). Thus, absorptive capacity is a crucial channel for creating new and maintaining existing competitive advantages.

This article outlines most important research trends in the theoretical and practical discussion of absorptive capacity. Applying a bibliometric analysis, we start with describing the historical development of the absorptive capacity research. Afterward, we define the intellectual core of the absorptive capacity concept and discuss the recent conceptualizations. We identify two prominent streams in the management literature that are specifically linked to the concept of absorptive capacity and provide a new approach on how to integrate the two streams. The article ends with an outlook into the future of the absorptive capacity research.

Absorptive Capacity

Absorptive capacity was originally defined as a firm's ability to recognize the value of new information, assimilate it, and apply it for commercial purposes (Cohen and Levinthal, 1990). Cohen and Levinthal's (1989, 1990) notion of absorptive capacity refers to the understanding of R&D investments being not only important for creating inventions but also to the ability of a firm to internalize knowledge from external sources (Schildt et al., 2012). Since these early contributions, there have been an increasing number of articles. We applied bibliometric methods for analyzing the existing research. We first tracked the citations of the two seminal contributions by Cohen and Levinthal (1989, 1990). We second identified articles using 'absorptive capacity' as one of the keywords. We conducted the search in Scopus. The Scopus database was considered as more suitable than alternatives such as Web of Science or Google Scholar. The Web of Science database contains fewer journals than Scopus. Google Scholar has no advanced search function. The search results were merged into a master list of articles. By combining both lists, we checked for double entries and inconsistencies such as misspelled names or wrong publication years. The combination yielded 828 articles.

The second bibliographic method is citation analysis, which is an acceptable surrogate for the intellectual core of the absorptive capacity research (Culnan, 1986). We tracked the number of articles published per year, the journals, subject areas, and keywords. As shown in **Figure 1**, research on absorptive capacity is developing into a highly dynamic management discipline. The number of articles has increased steadily, with a late peak in 2012 and 2013, at 117 and 114 articles, respectively

The historical development of the absorptive capacity concept can be distinguished into three phases:

- *Phase 1*: Early emergence of the absorptive capacity concept (1989–2001)
- *Phase 2*: Conceptual foundation and establishment as a research domain (2002–07)
- *Phase 3*: Emergence of an important research domain in business research (2008–)

With the publication of Cohen and Levinthal's (1989, 1990) seminal articles, the concept of absorptive capacity had been formulated. As researchers and practitioners had quickly acknowledged absorptive capacity as a relevant concept to better understand organizational learning, knowledge

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73106-0

[1]– Number of articles per year using absorptive capacity as a key word. Database: Scopus.

Figure 1 Articles on absorptive capacity in the social science field.

management, R&D, innovation and competitive advantage, the concept was discussed, applied, and replicated in numerous contributions in the following years (Szulanski, 1996; Tsai, 2001). In the first phase, the concept gained momentum within management science.

In the early 2000s, the concept has been further developed with a number of important conceptual refinements and extensions. This period can be interpreted as a second phase, in which the absorptive capacity concept was established as an own research domain within the field of management research and organization theory. Central contributions in this period were among others articles by Zahra and George (2002), Jansen et al. (2005), Lane et al. (2006), and Todorova and Durisin (2007).

The third phase started at the end of the 2000s, when publications on the absorptive capacity concept were increasingly used as an approach to frame empirical research. In this enduring phase, the number of publications on the topic has experienced a substantial increase every year until a peak was reached in 2012 and 2013 with almost 120 annual publications. Various contributions inquired into the relationship between key constructs of the absorptive capacity concept. Other research aimed at gaining a better understanding of what role context conditions and other external factors played for absorptive capacity to have a significant impact on innovation performance. Contributions in this third phase include Lewin et al. (2011), Vasudeva and Anand (2011), Schildt et al. (2012), and Gebauer et al. (2012, 2014).

Five important keywords emerged from the analysis of keywords and subjects of the absorptive capacity articles. These are knowledge management (e.g., Lane and Lubatkin, 1998; Minbaeva et al., 2003; Vasudeva and Anand, 2011), organizational learning (e.g., Schildt et al., 2012), innovation management (e.g., Lichtenthaler and Lichtenthaler, 2009), research and development (Boschma and ter Wal, 2007; Stock et al., 2001), and competitive advantages (e.g., Lewin et al., 2011). Absorbing external knowledge requires adequate knowledge management and organizational learning processes. Having such processes in place to absorb external knowledge is essential for a company's innovation management and research and development. Due to the effect of these processes, it is argued that absorptive capacity is a key driver for gaining a competitive advantage.

All five components are highly relevant for the absorptive capacity concepts. However, as indicated in **Figure 2**, the relative importance of each component has changed across the three phases. Whereas the relative importance of knowledge management, innovation management, and research and development has increased, articles on absorptive capacity put less emphasis on organizational learning and competitive advantage.

Knowledge management, innovation management, and research and development cover increasingly diverse research themes. Innovation management had initially a relative narrow focus, but has now been extended to include discussions on innovation performance and open innovation into the concept of absorptive capacity (e.g., Boschma and ter Wal, 2007; Lichtenthaler and Lichtenthaler, 2009). Knowledge management has diversified into themes such as knowledge transfer, knowledge-based systems, knowledge acquisition, knowledge sharing, and human capital (e.g., Gebauer et al., 2012, 2014; Minbaeva et al., 2003; Shenkar and Li, 1999; Vasudeva and Anand, 2011). Articles on research and development have linked absorptive capacity to technology transfer, patents, and inventions (e.g., Grünfeld, 2003; Stock et al., 2001).

As indicated in **Figure 2**, absorptive capacity is also related to many other topics. In phase 3, for example, there have been 17 articles about the link between absorptive capacity and dynamic capabilities. These articles embedded absorptive capacity in the debate on dynamic capabilities, which originates from the evolutionary theory of the firm (Zollo and Winter, 2002). Dynamic capabilities enable companies to respond to changes in the business environment. A similar argumentation is used for the absorptive capacity concept.

Figure 2 Main themes across the phases of absorptive capacity research.

With its focus on a firm's ability to recognize, assimilate, and apply external knowledge, the concept of absorptive capacity has a strong link to the literature on dynamic capabilities, where the reconfiguring of existing knowledge structures is a defining characteristic.

Among the 828 articles, we selected those with 100 and more citations. Applying the threshold of 100 citations leads to a core set of 26 most influential contributions to the absorptive capacity concept (Intellectual core of absorptive capacity). This core is informed purely by academic papers indicating the strong research interest in the topic. These papers are published in most prominent journals such as Strategic Management Journal, Academy of Management Journal, Academy of Management Review, and Administrative Science Quarterly among others. The 26 articles account for 72.8% of the total number of citations in the entire set of the 828 articles published on absorptive capacity.

Recent Developments in Absorptive Capacity Research

Conceptualization of Absorptive Capacity

Since the original definition, various conceptualizations of absorptive capacity have emerged (e.g., Lane et al., 2006; Lewin et al., 2011; Gebauer et al., 2012). While the early conceptualizations focused on R&D-related issues, later research broadened the concept to developing absorptive capacity at the organizational level (Tsai, 2001). The term knowledge within the absorptive capacity concept subsumes both procedural and declarative knowledge. The latter provides a description of state such as information on customer needs, technological trends, and strategic plans and refers to the notion of know-what. Procedural knowledge describes the current practices inside a firm such as the tools and processes that companies use to determine customer needs, extrapolate technological trends, and formulate strategic responses (Kogut and Zander, 1992). The notion of know-how captures procedural knowledge. There are several dimensions along which the absorptive capacity concept has evolved.

Taking a very general perspective, a number of existing conceptualizations describe absorptive capacity as the independent variable and innovation performance as the dependent variable. Such a view tends to capture absorptive capacity as an aggregated construct. It hardly allows researchers to explain the underlying processes of absorptive capacity at the firm level. Yet, aggregated concepts enable scholars to theorize and empirically test how variances of the firm-level characteristics, specific determinants, and context conditions of absorptive capacity affect innovation performance. Some of these general conceptualizations entail moderators, which can either strengthen or weaken the relationships between absorptive capacity and innovation outcomes. For example, Van den Bosch et al. (1999) propose business strategy as such a moderator. A first-mover strategy yields advantages when it involves building up absorptive capacity. By contrast, a follower strategy requires lower absorptive capacity. Similarly, Tsai (2001) argues that the centrality of a company's position in the knowledge network strengthens the impact of absorptive capacity on performance.

In contrast to the variance models, other research on absorptive capacity has defined the research agenda in this field over the past years. This stream focused on detailing the underlying processes of absorptive capacity. This led to a clearer understanding of the nature of absorptive capacity and resulted in the emergence of various process models. Zahra and George (2002) introduced the distinction of absorptive capacity into potential absorptive capacity and realized absorptive capacity. The former captures knowledge acquisition and assimilation, which refer to a firm's capacity to identify and acquire externally generated knowledge. Realized absorptive capacity refers to the capacity to transform and exploit the knowledge for

commercial purposes. The literature is contradictory on the sequence of knowledge absorption. Zahra and George (2002) and Jansen et al. (2005) conceptualize the sequence as a linear relationship between acquisition, assimilation, transformation, and exploitation, whereas Todorova and Durisin (2007) interpret assimilation and transformation as two parallel elements. Knowledge is assimilated, if the existing cognitive structure of organizational members does not change. Transformation means that new knowledge is interrelated with changing existing cognitive structures.

Independent of the sequence of knowledge assimilation and transformation, potential and realized absorptive capacity are linked through an efficiency factor. A higher efficiency factor leads to greater innovation performance because organizations pursue a course of action in response to their potential knowledge (Zahra and George, 2002). According to the efficiency factor, Winter (2000) suggests that satisficing rather than optimizing guides managers in transforming potential into realized knowledge. According to this argument, knowledge stocks accumulated through potential absorptive capacity function as strategic reference points and aspiration levels.

An important aspect of the process models is that they enable scholars to conceptualize and therefore capture learning processes as one of the central underlying elements of absorptive capacity. With the increasing emphasis on learning processes, the absorptive capacity literature has recently developed close links to two other streams in the management strategy and organization theory literature; on the one hand, the literature on interorganizational knowledge transfer and learning and on the other hand, the literature on dynamic capabilities with its focus on sustained competitive advantage through processes of learning and change. In the following, we present some contributions on absorptive capacity in the light of these two streams in management research and present the implications of these contributions.

Absorptive Capacity and Learning Processes

Both potential and realized absorptive capacities are cumulative and depend on past experiences. Past experience and prior knowledge are key elements in the absorptive capacity concept. Prior R&D investments – and therefore prior knowledge – determine at the firm level the extent and diversity at which an organization is able to recognize and understand, assimilate, transform, and apply knowledge from a variety of external sources. Thus, the starting point for a firm to absorb external knowledge and the kind of knowledge that a firm absorbs are cumulative and path dependent. This has a number of implications.

One implication is that efforts to develop absorptive capacity in one period make it easier to accumulate it in the next period (Cohen and Levinthal, 1990). Accordingly, absorptive capacity is not static, but rather evolves through learning processes (Lane et al., 2006; Todorova and Durisin, 2007). Lane et al. (2006) conceptualize absorptive capacity as a firm's ability to utilize external knowledge through three sequential learning processes: exploratory, transformative, and exploitative. Exploratory learning is about the acquisition of external knowledge and corresponds to the notion of potential absorptive capacity. Through exploitative learning, companies can apply acquired knowledge and therefore combine existing knowledge with newly generated knowledge. Such learning reflects the concept of realized absorptive capacity. Transformative learning links the exploratory and exploitative learning processes. It can span from maintaining and reactivating knowledge to conversion and combination of knowledge (Flatten et al., 2011).

Camisón and Forés (2010) extend that perspective on transformative learning further. The authors describe transformative learning as developing and refining "… the internal routines that facilitate the transference and combination of previous knowledge with the newly acquired or assimilated knowledge. Transformation may be achieved by adding or eliminating knowledge, or by interpreting and combining existing knowledge in a different, innovative way" (Camisón and Forés, 2010: p. 709).

Alternatively, exploratory and exploitative learning processes can be linked through assimilative learning. The term assimilation is more about integrating this knowledge into the organizational knowledge base. Considering the dynamic capability perspective, exploratory and transformative learning are of particular importance in turbulent environments.

Another dimension of interorganizational knowledge transfer and learning is directly linked to the knowledge base on which absorptive capacity is built. In a recent contribution, Vasudeva and Anand (2011) highlight the distinction between latitudinal and longitudinal absorptive capacity. "[L]atidudinal absorptive capacity processes and uses diverse knowledge, and longitudinal absorptive capacity processes and uses distant knowledge" (Vasudeva and Anand, 2011: p. 612). This is an important distinction and a further development of the absorptive capacity concept because it decomposes absorptive capacity into qualitatively different parts. In fact, this distinction specifies the path dependency of absorptive capacity. If the two components are linked to different search approaches, then this has the implication that a firm may not only have too little absorptive capacity in general but may also have an imbalance (or suboptimal) composition of latitudinal and longitudinal absorptive capacity. Consequently, a firm may be restricted regarding the knowledge that it can absorb. This, in turn, determines the breadth of areas, from which a firm can absorb knowledge and subsequently develop new knowledge and innovation. In this sense, the concept of absorptive capacity is closely related to interorganizational learning and knowledge transfer and the internal capacities to recognize and access this knowledge.

Absorptive Capacity and Dynamic Capabilities

The concept of absorptive capacity is also embedded in the debate on dynamic capabilities (Teece et al., 1997; Zollo and Winter, 2002). The debate on capabilities originates from the resource-based view of the firm. Organizational capabilities are firm-specific resources and processes to accomplish strategic goals by utilizing the available know-how and nonfirm-specific resources (e.g., Teece et al., 1997; Zollo and Winter, 2002). One of the most prevalent terms for capabilities is the distinction into operational and dynamic capabilities (Teece et al., 1997).

Operational capabilities comprise the competences and skills that determine a firm's efficiency and effectiveness in executing its current business activities and in accomplishing specific tasks (Zahra et al., 2006). Dynamic capabilities encapsulate the evolutionary nature of resources in firm organizations (Teece et al., 1997; Zahra and George, 2002). Dynamic capabilities enable companies to respond to changes in the business environment and change their operational capabilities accordingly. Teece et al. (1997: p. 516) defined dynamic capabilities as "… the firm's ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments." Zollo and Winter (2002: p. 340) specify the meaning of dynamic capabilities as being "… a learned and stable pattern of collective activity through which the organization systematically generates and modifies its operating routines in pursuit of improved effectiveness …". In fact, dynamic capabilities define an organization's ability to identify the need for change, formulate an appropriate response, and implement a course of action.

Dynamic capabilities avoid a competence trap, in which competences become irrelevant due to changes in the business environment. Zahra et al. (2006: p. 918) define dynamic capabilities as the managerial ability "to reconfigure a firm's resources and routines in the manner envisioned and deemed appropriate." Dynamic capabilities are beneficial in highly turbulent settings (Zahra et al., 2006).

As seen in more detail below, it is exactly in this context of distinguishing between operational and dynamic capabilities to interpret the relationship between absorptive capacity as learning and knowledge transfer processes and the dynamic capabilities as a higher level concept. As absorptive capacity is defined as a firm's ability to recognize, assimilate, and apply external knowledge, it can be interpreted in the context of dynamic capabilities and specifically in the context of being a concept that underpins the conditions to generate the level of adaptability that is required for adjusting and reconfiguring the absorptive capacity and its corresponding processes at the organizational level to acquire new knowledge from external sources. Some recent contributions in the absorptive capacity literature have highlighted this link (e.g., Lewin et al., 2011; but also Lane et al., 2006).

In sum, there have been significant developments at the conceptual level of absorptive capacity with some recent contributions on interorganizational knowledge transfer and dynamic capabilities. However, both streams lack some aspects. The interorganizational learning approach is relatively quiet about the capabilities required to structure and configure the adequate absorptive capacity processes. The capability approach, in contrast, remains often on a relatively general conceptual level without making the links to the various absorptive capacity processes (i.e., acquisition, assimilation, transformation, exploitation) explicit. In the next section, we provide an approach how to integrate the two streams and provide an interesting new view of absorptive capacity as learning and adaptation processes with a link to dynamic capabilities. **Table 1** summarizes the most prominent conceptualization of absorptive capacity.

Table 1 Most prominent conceptualization of absorptive capacity

Conceptualization of absorptive capacity as…	*Description of the conceptualization*	*References*
Aggregated concept	● Absorptive capacity as independent variable, innovation performance as dependent variable ● Allows inquiring how variances of firm-level characteristics and context conditions of absorptive capacity affect innovation performance ● Business strategy as moderator (Van den Bosch et al., 1999) ● Company's position in the knowledge network as moderator (Tsai, 2001)	Van den Bosch et al. (1999), Tsai (2001)
Learning process	● Absorptive capacity evolves through learning processes ● Typical phases of the learning process are knowledge recognition and acquisition, knowledge assimilation, knowledge transformation, knowledge exploitation ● Prior knowledge as base for learning processes ● Refinement of the absorptive capacity concept by distinguishing various types of knowledge that a company aims to absorb and process: e.g., diverse vs distant knowledge (Vasudeva and Anand, 2011)	Zahra and George (2002), Lane et al. (2006), Jansen et al. (2005), Todorova and Durisin (2007), Vasudeva and Anand (2011)
Learning process configured through dynamic capabilities	● Absorptive capacity evolves through learning processes with firms requiring capabilities (dynamic capabilities) to build, configure, and reconfigure these learning processes ● Dynamic capabilities were initially understood as strategic context conditions driving and influencing the absorptive capacity process (e.g., Lane et al., 2006) ● Recently, dynamic capabilities have been understood as endogenous part of the absorptive capacity concept as interrelated learning processes conceptualized as combinative capabilities (e.g., Gebauer et al., 2012) and Metaroutines (e.g., Lewin et al., 2011)	Lane et al. (2006), Lewin et al. (2011), Gebauer et al. (2012)

Integrating Dynamic Capabilities into the Conceptualization of Absorptive Capacity

One way to bring the two streams together is to conceptualize the capabilities required in various process phases of absorptive capacity as operational capabilities and interpret combinative capabilities as dynamic capabilities. More specifically, the absorptive capacity's learning processes interact with combinative capabilities, which describe how a company systematizes, socializes, and coordinates knowledge (Zollo and Winter, 2002). Systemizing, coordinating, and socializing knowledge can either contribute to or hinder learning processes at the corresponding level of absorptive capacity (Van den Bosch et al., 1999). Coordinating knowledge refers to cross-functional interfaces and participation in decision processes. Knowledge can be systematized by the formalization and routinization of organizational actions. The socialization of knowledge is based on the density of social linkages (structural aspects) and shared social experience (cognitive aspects) in an organization and between the organization and its external partners (e.g., customers, suppliers) (Van den Bosch et al., 1999; Jansen et al., 2005).

This argumentation indicates that increasing the level of external knowledge does not always enhance innovation. More important is how combinative capabilities interact with learning processes of the absorptive capacity process. The key point is that creating an in-depth understanding of the interaction between learning processes and combinative capabilities could also explain why, in similar business environments, some companies achieve greater competitive advantages than others, through converting external knowledge into strategic innovations. That is because companies may differ in the dynamic capabilities they possess to reconfiguring the learning and knowledge transfer in the absorptive capacity process.

Figure 3 presents the new conceptualization. Against this background, past experiences set the reference points for developing absorptive capacity. The degree of strategic innovation is the dependent variable. Learning processes (exploratory, assimilative, transformative, and exploitative learning processes) driving absorptive capacity form the independent variable. Combinative capabilities (systematization, coordination, and socialization) mediate the relationship between learning processes and innovation outcomes, whereas strategy and network position are considered as moderating the evolution of learning processes and combinative capabilities.

Implications and Outlook

The integrated view presented in the previous section has a number of implications. It allows us to address some new aspects, provides an outlook on emerging topics, and lays out some directions for future research. This new approach enriches the theoretical knowledge on relationships between absorptive capacity, learning processes, combinative capabilities, and (strategic) innovations. The general contribution is twofold.

Firstly, using strategic innovation as the dependent variable, the absorptive capacity conceptualization includes the interactions of learning processes and combinative capabilities and as such forms the independent variable. Therefore, this conceptualization departs from the existing preoccupation

Figure 3 Dynamic capabilities, absorptive capacity, and learning processes: a new conceptualization (Gebauer, H., Worch, H., Truffer, B., 2012. Absorptive capacity, learning processes and combinative capabilities as determinants of strategic innovation. European Management Journal 30 (1), 57–73). Adapted from Lane, P.J., Koka, B.R., Pathak, S., 2006. The reification of absorptive capacity: a critical review and rejuvenation of the construct. Academy of Management Review 31 (4), 833–863; Zahra, S.A.S., George, G.G., 2002. Absorptive capacity: a review, conceptualization, and extension. Academy of Management Review 27 (2), 185–203; Zollo, M., Winter, S.G., 2002. Deliberate learning and the evolution of dynamic capabilities. Organization Science 13 (3), 339–351.

with absorptive capacity having direct innovation outcomes. This insight is in the tradition of Lane et al. (2006), but includes dynamic capabilities as independent variable rather than solely as a context condition.

Secondly, to explain how the necessary knowledge for strategic innovation is absorbed, our approach provides an understanding of how learning processes and combinative capabilities contribute to strategic innovation. The conceptualization suggests that assumptions on strategic behavior, network position, and the sequence of learning processes need to be reconsidered. This new view has implications and allows us to reconsider (and reinterpret) some findings in the absorptive capacity literature.

For example, one implication is that the argument that first-mover strategies have advantages for a company's absorptive capacity cannot easily be transferred as a proposition for strategic innovation (Van den Bosch et al., 1999). Recent findings suggest that follower strategies seem beneficial, where first-mover strategies would generate counter-productive side effects (Gebauer et al., 2012, 2014). The reasons for such side effects are constraints on a firm's combinative capabilities, which are necessary for taking advantage of the exploratory learning processes. First-mover strategies seem to hinder the departure from a strong formalization of knowledge sharing. This, in turn, constrains the development of diverse combinative capabilities such as a broader range of problem-solving skills, a higher cognitive diversity across the management team, and moving away from vertically centralized decision-making authority. Therefore, the new approach suggests that a first-mover strategy can also hinder strategic innovations, whereas a follower strategy could enhance strategic innovation due to a more broadly underpinned – though time intensive – innovation process. Further theory-building and empirical research should elaborate how a first-mover strategy can form rigidities, which constrain strategic innovations.

Similar to the first-mover strategy, Tsai (2001) argues that a more central network position strengthens the relationship between absorptive capacity and innovation performance. Yet recent findings indicate that a central network position and strong ties with network partners tend – under certain circumstances – to constrain the knowledge creation process (Gebauer et al., 2012, 2014). This is because centrality in a network may be important to shape the interpretations and the use of knowledge, but less in perceiving new perspectives that would allow a firm to have new interpretations of its existing knowledge. Therefore, the new approach summarized in **Figure 3** suggests that increasing centrality in the network position tends to constrain strategic innovation. Further theory-building and empirical research should elaborate how centrality in the network position leads to strategic reference points, which limit the knowledge creation process and ultimately innovation performance.

The new approach also sheds light on the discussion of the sequence of the acquisition, assimilation, transformation, and exploitation of knowledge (Jansen et al., 2005; Todorova and Durisin, 2007; Zahra and George, 2002). Assimilation and transformation are not sequential, but also not necessarily parallel. As recent findings show (Gebauer et al., 2012, 2014), if the exploratory learning processes rely predominantly on previous combinative capabilities, they will not only lead to some ideas that are relatively close to the existing knowledge base, but will also assimilate, rather than transform the knowledge. Under such conditions, exploratory learning processes are preceded by an assimilation of the newly acquired knowledge. Assimilation continues with previous combinative capabilities. Other reconfigurations of combinative capabilities within the exploratory learning process may enable transformation, in which the newly acquired knowledge interacts with changes in combinative capabilities. Therefore, this conceptualization suggests that transformative learning plays a key role in strategic innovation and contributes significantly to strategic innovation.

Finally, departing from existing configurations in combinative capabilities suggests that absorptive capacity also involves the unlearning of capabilities. Adding to Todorova and Durisin's (2007: p. 777) argument that "…firms often fail to identify and absorb valuable new external knowledge, because they are hampered by their embedded knowledge base, rigid capabilities, and path dependent managerial cognition…", rigidities exist specifically in how knowledge is systematized, coordinated, and socialized. We propose that firms reconfigure their combinative capabilities. For example, exploratory and transformative learning processes benefit from decreased formalization and more interdisciplinary routines for knowledge systematization, cross-functional interfaces, job rotation, and an umbrella strategy for knowledge coordination, as well as increased cognitive diversity and more dense social linkages. While these reconfigurations essentially depart from past experiences, relying on initial systematization capabilities would promote exploitative learning processes.

The results support the argument that the socialization of knowledge influences all three learning processes (Jansen et al., 2005), and not only the impact of potential on realized absorptive capacity, as proposed by Zahra and George (2002). This line of argumentation is not restricted to the socialization of knowledge, but also includes its systematization and coordination. Furthermore, the findings support the feedback process perspective on absorptive capacity (Lane et al., 2006; Todorova and Durisin, 2007), and depart from the linear approach to absorptive capacity (Jansen et al., 2005; Zahra and George, 2002). Thus, the new approach suggests that combinative capabilities enhance exploratory and transformative learning. Further theory-building and empirical research should elaborate how combinative capabilities facilitate these learning processes and specifically enhance exploratory and transformative learning.

Abstract

What explains individual differences in academic achievement motivation? This article outlines the answer to question in terms of three basic questions students ask themselves: Can I succeed? Do I want to do this task? And, Why am I doing this task? To the extent that individuals have positive answers to each of these questions, they will be motivated to achieve. The developmental origins of individuals' answers to these questions are summarized. In addition, specific achievement motivation pathologies (e.g., test anxiety and learned helplessness) are discussed.

Over the years, psychologists have proposed many different components of academic motivation (see Weiner, 1992 for full discussion of history of this field). Historically, this work began with efforts to understand and formalize the role of the basic need of achievement for human drive, the introduction of the idea of competence motivation, and early work on expectancies and social learning. Developmentalists such as Vaugh and Virginia Crandall, Battle, and Heckhausen translated these ideas into a developmental framework for studying the origins of individual differences in achievement motivation (e.g., Battle, 1966; Crandall, 1969; Crandall et al., 1962; Heckhausen, 1968). Sarason and his colleagues elaborated the concept test anxiety, developed measures, and outlined a developmental theory to explain the origins of individual differences in this critical component of academic achievement motivation (e.g., Sarason et al., 1960; Hill and Sarason, 1966).

Through this early period, the focus was on achievement motivation as a drive and need. With the cognitive revolution of the 1960s, researchers shifted to a much more cognitive view of motivation. Largely through the work of Weiner, attribution theory became the central organizing framework (see Weiner, 1992). This article falls in this cognitive tradition.

Eccles et al. (1998) suggested that one could group these various components under three basic questions: Can I succeed at this task? Do I want to do this task? Why am I doing this task? Children who develop positive and/or productive answers to these questions are likely to engage their school work and to thrive in their school settings more than children who develop less positive and/or noneffectual answers.

Can I Succeed?

Eccles and her colleagues' expectancy – value model of achievement-related choices and engagement, (see Eccles et al., 1998) is depicted in **Figure 1**. Expectancies and values are assumed to directly influence performance, persistence, and task choice. Expectancies and values are assumed to be influenced by task-specific beliefs such as perceptions of competence, perceptions of the difficulty of different task, and individuals' goals and self-schema. These social cognitive variables, in turn, are influenced by individuals' perceptions of other peoples' attitudes and expectations for them, by their own interpretations of their previous achievement outcomes, and by their affective memories of, or affective expectations about, similar tasks. Individuals' task-perceptions and interpretations of their past outcomes are assumed to be influenced by socializer's behavior and beliefs, by their own histories of success and failure, and by cultural milieu and unique historical events.

Bandura (1997) proposed a social cognitive model of motivated behavior that also emphasizes the role of perceptions of efficacy and human agency in determining individuals' achievement strivings. He defined self-efficacy as individuals' confidence in their ability to organize and execute a given course of action to solve a problem or accomplish a task. Bandura proposed that individuals' efficacy expectations (also called perceived self-efficacy) are determined by: previous performance (people who succeed will develop a stronger sense of personal efficacy than those who do not); vicarious learning (watching a model succeed on a task will improve one's own self-efficacy regarding the task); verbal encouragement by others, and the level of one's physiological reaction to a task or situation.

Bandura (1997) proposed specific development precursors of self-efficacy. First, through experiences controlling immediate situations and activities, infants learn that they can influence and control their environments. If adults do not provide infants with these experiences, they are not likely to develop as strong a sense of personal agency. Second, because self-efficacy requires the understanding that the self produced an action and an outcome, Bandura argued that a more mature sense of self-efficacy should not emerge until children have at least a rudimentary self-concept and can recognize that they are distinct individuals – which happens sometime during the second year of life. Through the preschool period, children are exposed to extensive performance information that should be crucial to their emerging sense of self-efficacy. However, just how useful such information is likely depends on the child's ability to integrate it across time, contexts, and domains. Since these cognitive capacities emerge gradually over the preschool and early elementary school years, young children's efficacy judgments should depend more on immediate and apparent outcomes than on a systematic analysis of their performance history in similar situations.

Figure 1 Model of Achievement Goals.

The Development of Competence-related/ Efficacy Beliefs

Changes in Children's Understanding of Competence-related Beliefs

Nicholls asked children questions about ability, intelligence, effort, and task difficulty, and how different levels of performance can occur when children exert similar effort (e.g., Nicholls, 1990). He found four relatively distinct levels of reasoning: Level One (ages 5 to 6) – effort, ability, and performance are not clearly differentiated in terms of cause and effect; Level Two (ages 7 to 9) – effort is seen as the primary cause of performance outcomes; Level Three (ages 9 to 12) – children begin to differentiate ability and effort as causes of outcomes; Level Four – adolescents clearly differentiate ability and effort. They understand the notion of ability as capacity and believe that ability can limit the effects of additional effort on performance, that ability and effort are often related to each other in a compensatory manner, and, consequently, that a successful outcome that required a great deal of effort likely reflects limited ability.

Change in the Mean Level of Children's Competence-related Beliefs

Children's competence-related beliefs decline across the school years (see Eccles et al., 1998). To illustrate, in Nicholls (1979) most first graders (6 years old) ranked themselves near the top of the class in reading ability, and there was essentially no correlation between their ability ratings and their performance level. In contrast, the 12-year-olds' ratings were more dispersed, and their correlation with school grades was 70 or higher. Expectancies for success also decrease during the elementary and secondary school years. In most laboratory-type studies, 4- and 5- year old children expect to do quite well on a specific task, even after repeatedly failing (Parsons and Ruble, 1977). Across the elementary school years, the mean levels of children's expectancies for success both decline and become more sensitive to both success and failure experiences.

These studies suggest that most children begin elementary school with quite optimistic ability-related self-perceptions and expectations, and that these beliefs decline rather dramatically as the children get older. In part this drop reflects the initially high, and often unrealistic, expectations of kindergarten and first- grade children. Other changes also contribute to this decline – changes such as increased exposure to failure feedback, increased ability to integrate success and failure information across time to form expectations more closely linked with experience, increased ability to use social comparison information, and increased exposure to teachers' expectations.

Some of these changes are also linked to the transition into elementary school. Entrance into elementary school and then the transition from kindergarten to first grade introduces several systematic changes in children's social worlds. First, classes are age stratified, making within-age-ability social comparison much easier. Second, formal evaluations of competence by 'experts' begin. Third, formal ability grouping begins usually with reading group assignment. Fourth, peers have the opportunity to play a much more constant and salient role in children's lives. Each of these changes should impact children's motivation. Parents' expectations for, and perceptions of, their children's academic competence are also influenced by report card marks and standardized test scores given out during the early elementary school years, particularly for mathematics (Alexander and Entwisle, 1988).

There are significant long-term consequences of children's experiences in the first grade, particularly experiences associated with ability grouping and within class differential teacher treatment. For example, teachers use a variety of information to assign first graders to reading groups including temperamental characteristics like interest and persistence, race, gender, and social class. Alexander et al. (1993) demonstrated that differences in first-grade reading group placement and teacher-student interactions have a significant effect (after controlling for initial individual differences in competence) on motivation and achievement several years later. Furthermore, these effects are mediated by both differential instruction and the impact of ability-group placement on parents' and teachers' views of the children's abilities, talents, and motivation (Pallas et al., 1994).

Theories Concerned With the Question 'Do I Want to Do This Task?'

Subjective Task Values

Eccles et al. (1983) outlined four motivational components of subjective task value: attainment value, intrinsic value, utility value, and cost. Attainment value is the personal importance of doing well on the task. Intrinsic value is the enjoyment the individual gets from performing the activity, or the subjective interest the individual has in the subject. Utility value is how well a task relates to current and future goals, such as career goals. Finally, they conceptualized 'cost' in terms of the negative aspects of engaging in the task (e.g., performance anxiety and fear of both failure and success), as well as both the amount of effort that is needed to succeed and the lost opportunities resulting from making one choice rather than another.

Eccles and her colleagues have shown that ability self-concepts and performance expectancies predict performance in mathematics and English, whereas task values predict course plans and enrollment decisions in mathematics, physics, English, and involvement in sport activities even after controlling for prior performance levels (see Eccles et al., 1998). They have also shown that values predict career choices.

Development of Subjective Task Values

Eccles and their colleagues have documented that even young children distinguish between their competence beliefs and their task values. They have also shown that children's and adolescents' valuing of certain academic tasks and school subjects decline with age.

Although little developmental work has been done on this issue, it is likely that there are differences across age in which of the components of achievement values are most dominant motivators. Wigfield and Eccles (1992) suggested that interest is especially salient during the early elementary school grades. If so, then young children's choice of different activities may be most directly related to their interests. And if young children's interests shift as rapidly as their attention spans, it is likely they will try many different activities for a short time each before developing a more stable opinion regarding which activities they enjoy the most. As children get older the perceived utility and personal importance of different tasks likely become more salient, particularly as they develop more stable self-schema and long-range goals and plans.

A third important developmental question is how children's developing competence beliefs relate to their developing subjective task values? According to both the Eccles et al. model and Bandura's self-efficacy theory, ability self-concepts should influence the development of task values. Mac Iver et al. (1991) found that changes in junior high school (ages 11 – 13) students' competence beliefs over a semester predicted changes in children's interests much more strongly than vice versa. Does the same causal ordering occur in younger children? Wigfield (1994) proposed that young children's competence and task-value beliefs are likely to be relatively independent of each other. This independence would mean that children might pursue some activities in which they are interested regardless of how good or bad they think they are at the activity. Over time, particularly in the achievement domain, children may begin to attach more value to activities on which they do well, for several reasons: first, through process associated with classical conditioning, the positive affect one experiences when one does well should become attached to the activities yielding success. Second, lowering the value one attaches to activities that one is having difficulty with is likely to be an effective way to maintain a positive global source of efficacy and self-esteem. Thus, at some point the two kinds of beliefs should become more positively related to one another.

Interest Theories

Closely related to the intrinsic interest component of subjective task value is the work on 'interest' (Renninger et al., 1992). Researchers in this tradition differentiate between individual and situational interest. Individual interest is a relatively stable evaluative orientation towards certain domains; situational interest is an emotional state aroused by specific features of an activity or a task. The research on individual interest has focused on its relation to the quality of learning. In general, there are significant but moderate relations between interest and text learning. More importantly, interest is more strongly and positively related to indicators of deep-level learning (e.g., recall of main ideas, coherence of recall, responding to deeper comprehension questions, representation of meaning) than to surface-level learning (e.g., responding to simple questions, verbatim representation of text). The research on situational interest has focused on the characteristics of academic tasks that create interest. Among others, the following text features arouse situational interest: personal relevance, novelty, and comprehensibility.

Developmental Changes in Interest

Several researchers have found that individual interest in different subject areas at school declines continuously during the school years. This is especially true for the natural sciences. These researchers have identified changes in the following instructional variables as contributing to these declines: clarity of presentation, monitoring of what happens in the classroom, supportive behavior, cognitively stimulating experiences, self-concept of the teacher [educator vs scientist], and achievement pressure.

Intrinsic Motivation Theories

Over the last 25 years, studies have documented the debilitating effects of extrinsic incentives on the motivation to perform even inherently interesting activities (Deci and Ryan 1985). This has stimulated interest in intrinsic motivation. Deci and Ryan (1985) argue that intrinsic motivation is maintained only when actors feels competent and self-determined. Deci and Ryan (1985) also argue that the basic needs for competence and self-determination play a role in more extrinsically motivated behavior. Consider, for example, a student who consciously and without any external pressure selects a specific major because it will help him earn a lot of money. This student is guided by his basic needs for competence and self-determination but his choice of major is based on reasons totally extrinsic to the major itself. Finally, Deci and Ryan postulate that a basic need for interpersonal relatedness explains why people turn external goals into internal goals through internalization.

Developmental Changes in Intrinsic Motivation

Like interest and subjective task value intrinsic motivation declines over the school years (see Eccles et al., 1998), particularly during the early adolescent years (which coincide in many countries with the transition into upper-level educational institutions). Such changes lead to decreased school engagement. The possible origins of these declines have not been studied but are likely to be similar to the causes of declines in expectations, ability-related self-confidence and interest – namely, shifts in the nature of instruction across grade levels, cumulative experiences of failure, and increasing cognitive sophistication.

Why Am I Doing This?

The newest area of motivation is goal theory. This work focuses on why the children think they are engaging in particular achievement-related activities and what they hope to accomplish through their engagement. Several different approaches to goal theory have emerged. For instance, Schunk (1991) focuses on goals' proximity, specificity, and level of challenge and has shown that specific, proximal, and somewhat challenging goals promote both self-efficacy and improved performance. Other researchers have defined and investigated broader goal orientations. Nicholls and his colleagues (Nicholls, 1990) defined two major kinds of motivationally relevant goal patterns or orientations: ego-involved goals and task-involved goals. Individuals with ego-involved goals seek to maximize favorable evaluations of their competence and minimize negative evaluations of competence. Questions like 'Will I look smart?' and 'Can I outperform others?' reflect ego-involved goals. In contrast, with task-involved goals, individuals focus on mastering tasks and increasing their competence. Questions such as 'How can I do this task?' and 'What will I learn?' reflect task-involved goals. Dweck and her colleagues provide a complementary analysis distinguishing between performance goals (like ego-involved goals), and learning goals (like task-involved goals) (Dweck and Leggett, 1988). Similarly, Ames (1992) distinguishes between the association of performance (like ego-involved) goals and mastery goals (like task-focused goals) with both performance and task choice. With ego-involved (or performance) goals, children try to outperform others, and are more likely to do tasks they know they can do. Task-involved (or mastery-oriented) children choose challenging tasks and are more concerned with their own progress than with outperforming others.

Development of Children's Goals

To date there has been surprisingly little empirical work on how children's goals develop. Nicholls (1990) documented that both task goals and ego goals are already developed by second graders. However, Nicholls also suggested that the ego-goal orientation becomes more prominent for many children as they get older, in part because of developmental changes in their conceptions of ability and, in part, because of systematic changes in school context. Dweck and her colleagues (Dweck and Leggett, 1988) also predicted that performance goals should get more prominent as children go through school, because they develop a more 'entity' view of intelligence as they get older and children holding an entity view of intelligence are more likely to adopt performance goals.

It is also likely that the relation of goals to performance changes with age due to the changing meaning of ability and effort. In a series of studies looking at how competitive and noncompetitive conditions, and task and ego-focused conditions, influence pre- and elementary-school-aged children's interests, motivation, and self-evaluations, Butler (e.g., 1990) identified several developmental changes. First, competition decreased children's subsequent interest in a task only among children who had also developed a social-comparative sense of ability. Competition also increased older, but not younger, children's tendency to engage in social comparison. Second, although children of all ages engaged in social comparison, younger children seemed to be doing so more for task mastery reasons, whereas older children did so to assess their abilities. Third, whereas, 5, 7, and 10 year-old children's self-evaluations were quite accurate under mastery conditions, under competitive conditions 5- and 7-year-olds inflated their performance self-evaluations more than 10-year-olds.

The Development of Motivational Problems

Test Anxiety

Performance anxiety has been an important topic in motivational research from early on. In one of the first longitudinal studies, Hill and Sarason (1966) found that test anxiety both increases across the elementary and junior high school years and becomes more negatively related to subsequent grades and test scores. They also found that highly anxious children's achievement test scores were up to 2 years behind those of their low anxious peers and that girls' anxiety scores were higher than boys'. Finally, they found that test anxiety was a serious problem for many children.

High anxiety emerges when parents have overly high expectations and put too much pressure on their children (Wigfield and Eccles, 1989). Anxiety continues to develop in school as children face more frequent evaluation, social comparison, and (for some) experiences of failure; to the extent that schools emphasize these characteristics, anxiety become a problem for more children as they get older.

Anxiety Intervention Programs

Earlier intervention programs emphasized the emotionality aspect of anxiety and focused on various relaxation and desensitization techniques. Although these programs did succeed in reducing anxiety, they did not always lead to improved performance, and the studies had serious methodological flaws. Anxiety intervention programs linked to the worry aspect of anxiety focus on changing the negative, self-deprecating thoughts of anxious individuals and replacing them with more positive, task-focused thoughts. These programs have been more successful both in lowering anxiety and improving performance.

Learned Helplessness

Dweck and her colleagues initiated an extensive field of research on academic learned helplessness. They defined learned helplessness 'as a state when an individual perceives the termination of failure to be independent of his responses' (Dweck and Goetz, 1978: p. 157). They documented several differences between helpless and more mastery-oriented children's responses to failure. When confronted by difficulty (or failure), mastery-oriented children persist, stay focused on the task, and sometimes even use more sophisticated strategies. In contrast, helpless children's performance deteriorates, they ruminate about their difficulties, often begin to attribute their failures to lack of ability. Further, helpless children adopt an 'entity' view that their intelligence is fixed, whereas mastery-oriented children adopt an incremental view of intelligence.

In one of the few developmental studies of learned helpless behavior, Rholes et al. (1980) found that younger children did not show the same decrements in performance in response to failure as some older children do. However, Dweck and her colleagues' recent work (Burhans and Dweck, 1995) suggests that some young (5- and 6-year-old) children respond quite negatively to failure feedback, judging themselves to be bad people. These rather troubling findings show that negative responses to failure can develop quite early on.

What produces learned helplessness in children? Dweck and Goetz (1978) proposed that it depends on the kinds of feedback children receive from parents and teachers about their achievement outcomes, in particular whether children receive feedback that their failures are due to lack of ability. In Hokoda and Fincham (1995), mothers of helpless third-grade children (in comparison to mothers of mastery-oriented children) gave fewer positive affective comments to their children, were more likely to respond to their children's lack of confidence in their ability by telling them to quit, were less responsive to their children's bids for help, and did not focus them on mastery goals.

Alleviating Learned Helplessness

There are numerous studies designed to alleviate learned helplessness by changing attributions for success and failure so that learned helpless people learn to attribute failure to lack of effort rather than to lack of ability (see Fosterling, 1985). Various training techniques (including operant conditioning and providing specific attributional feedback) have been used successfully in changing children's failure attributions from lack of ability to lack of effort, improving their task persistence, and performance.

Self-efficacy training can also alleviate learned helplessness. Schunk and his colleagues (Schunk, 1994) have studied how to improve low-achieving children's academic performance through skill training, enhancement of self-efficacy, attribution retraining, and training children how to set goals. A number of findings have emerged from this work. First, the training increases both children's performance and their sense of self-efficacy. Second, attributing children's success to ability has a stronger impact on their self-efficacy than does either effort feedback, or ability and effort feedback. Third, training children to set proximal, specific, and somewhat challenging goals enhances their self-efficacy and performance. Fourth, training that emphasizes process goals (analogous to task or learning goals) increases self-efficacy and skills. Finally, combining strategy training, goal emphases, and feedback to show children how various strategies relate to their performance has a strong effect on subsequent self-efficacy and skill development.

Summary

In this article, a basic model of achievement motivation was presented and discussed. Developmental origins of individual differences in students' confidence in their ability to succeed, their desire to succeed, and their goals for achievement were summarized. To a large extent individual differences in achievement motivation are accounted for by these three beliefs. Most importantly, lack of confidence in one's ability to succeed and extrinsic (rather than intrinsic) motivation are directly related to the two major motivational problems in the academic achievement domain: test anxiety and learned helplessness. Specific interventions for these two motivational problems were discussed. Future research needs to focus on interconnections among the various aspects of achievement motivation. For example, how is confidence in one's ability to master academic tasks related to individuals' desire to master these tasks and to the extent to which the individual is intrinsically motivated to work towards mastery? More work is also needed on the impact of families, schools, and peers on the development of confidence, interest, and intrinsic motivation. Exactly how can parents and teachers support the development of high interest and high intrinsic motivation to work hard to master academic tasks? Finally, we need to know a lot more about the motivational factors that underlie ethnic and gender group differences in academic achievement patterns.

Academic Careers in Comparative Perspective

Abstract

In this article, we focus, from a comparative perspective, on the traditional academic career within a university setting. We commence by describing the various facets relevant to academic careers, including academic training, employment contracts, hierarchies, and the case for and against tenure. We conclude with a discussion of current reforms and policy debates.

The term 'academic career' is slippery to define. Most commonly, it refers to employment at universities by those educated at the doctoral level with the "triumvirate of teaching, research, and service" (Schuster and Finkelstein, 2006) as central employment responsibilities. Academic-like careers can also be found in other venues, including research institutes (e.g., CNRS in France, Max Planck Institutes in Germany, Russian Academy of Sciences), various levels of government, and arm's-length or nongovernmental organizations (e.g., OECD, UNESCO). For the purposes of this article, we focus, from a comparative perspective, on the traditional academic career within a university setting. We commence by describing the various facets relevant to academic careers, including academic training, employment contracts, hierarchies, and the case for and against tenure. We conclude with a discussion of current reforms and policy debates.

Academic Training

An academic career is characterized by an extended training period. Increasingly, the PhD is the entrance requirement for permanent teaching positions, research positions, or both and is now standard at most research universities in OECD countries. However, there is significant variation among academic systems regarding how the training period is conceptualized and interconnected with paid employment.

The range of doctoral training models is defined primarily in terms of the nature of the relationship – and the related degree of dependence – between the student and her or his research supervisory committee and the degree to which programs are structured. Doctoral programs fall on a continuum ranging from almost complete independence (i.e., 'reading' for a degree) where the student works independently with minimal contact and input from a research supervisor and committee and without a prescribed set of courses, to those that are highly structured, in terms of programs of study, and close surveillance by the research supervisory committee (Kehm, 2006). Most doctoral students are required to produce a dissertation that is 'original' theoretically, conceptually, and/or empirically. However, the nature and extent to which the dissertation is assessed – that is, whether examiners external to the supervisory committee, department, and university – varies from program to program (Usher, 2002).

Also, the extent of rigor, in terms of research training, varies across institutions and countries (Nerad and Heggelund, 2008). Programs offering full-fledged research training strive to ensure that, upon graduations, graduates are prepared to embark on research careers, and hence are intended for students who want to pursue this trajectory. Other programs are designed to provide credentials (and the related title of 'Dr') for individuals who seek to use such credentials as a signal in the labor market. As an illustration, in some countries (e.g., Austria, Germany), as late as 40 years ago, the doctorate was the first academic degree earned by university students. Clearly, it served a very different purpose than doctorates earned in highly differentiated university systems (e.g., the United States, UK). For example, Egon Franck and Christian Opitz (2007) demonstrate that 58.5% of CEOs of major German companies have earned doctorates, whereas only 5.5% of CEOs in comparable companies in the United States possess the same credential. The emphasis on labor market signaling can be regarded as problematic because of the potential to dilute the rigor of research training. This concern was the major impetus for a major redesign of doctoral programs in many European countries, in particular Germany, by refocusing the emphasis on research training (European University Association, 2007). However, that universities are accustomed to training academics for the nonacademic labor market can also be regarded as an advantage at a time where there is mismatch between supply and demand within academic labor markets (Nature, 2011; Usher, 2002).

The extent of rigor in doctoral examination policies, procedures, and practices also differentiates types of doctoral training. Efforts exerted by institutions to examine doctoral candidates range from minimal (e.g., dependent on one person, usually the research supervisor) to extensive (e.g., multiple checks and balances including external review of the dissertation, policies preventing conflicts of interest between the research committee and external examiners).

Doctoral training also serves as the interface between education and employment, with variation in the precise design of this interface. In many European countries, doctoral students may be formally employed by the university (e.g., Sweden). It is rare that the majority of doctoral students have an employment contract; usually, the most promising students are employed as assistants to their research supervisors. Those employed as assistants are regarded as 'early stage researchers'

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03001-4

in most European countries as defined by the Bergen Communiqué (European Ministers Responsible for Higher Education, 2005; Williams Committee of Inquiry into Education and Training, 1979). This type of employment is fixed term in nature and thus does not usually hold the promise of a permanent appointment upon successful completion of a doctoral degree. Because of the lack of rigor in some doctoral programs, many European systems require a second thesis, the *Habilitation*. In countries with a *Habilitation* system, fixed-term employment may also be the case while the junior academic works on her or his *Habilitation*. As with the doctoral degree, successful completion of a *Habilitation* does not lead to a permanent position. Rather, it is the opposite; by completing the *Habilitation*, many junior academics reach the maximum years allowed in fixed-term contracts and are required to leave the university (see chain contracts below).

Until recently, doctoral training in North America has been regarded predominantly as part of the education of prospective academics. Many doctoral students are employed as research or teaching assistants. Although they may be considered to be 'early stage' researchers (Bazeley, 2003), they are graduate students (and may belong to student unions) and not employees. Doctoral training in the United States and Canada is more rigorous than in most European higher education systems in terms of length, due to mandatory course work and other requirements such as comprehensive examinations. A doctoral degree is the necessary and sufficient formal entry requirement to an academic career. In North America, a maximum length of time to completion is usually specified, whereas in Europe, a minimal time to completion tends to be stipulated.

Employment Contracts

Employment contracts can be either permanent or fixed term. Senior academics typically have permanent positions. However, the dividing line between junior and senior academics and the criteria that define senior academics vary among academic systems.

In many countries, senior academics have tenure which guarantees higher job protection than does a regular permanent position (Finkin, 1996; Horn, 1999b). Because the case for and against tenure is complex and controversial, we devote a separate section to this topic. Types of tenure vary. Academics in most European countries are civil servants who can be terminated only under special circumstances; hence, they are accorded high job protection. However, in most instances only those holding a Professorship and Chair benefit from such protection. Academic tenure in North America is different in that even in the public universities of the United States and Canada, academics are not civil servants but rather employees of the university. Academic tenure in North America is the outcome of a long 'probation' period followed by rigorous peer review. This review involves peer review both within one's university (usually at the departmental, faculty, and university-wide levels) and externally by seeking expert opinions from academics from other universities. (In some countries, tenure status is not awarded to academics. For example, in the UK, tenure was abolished and replaced with permanent and fixed-term contracts, see Court (1998).)

There are different reasons for fixed-term contracts. First, fixed-term employment is used as a probation mechanism, usually in the early stages of an academic career. Under these circumstances, employees typically can look forward to the prospect of permanent employment if they stand the 'tenure' test. One example for this type of probation is the assistant professor within the North American tenure track system. The assistant professorship is a fixed-term position that concludes in an 'up or out' decision. A positive evaluation is required to achieve a permanent and tenured position.

In many European higher education systems, the term 'assistant' has a different meaning (Busch, 1963). Assistants in the German-speaking higher education systems are usually not on probation; they have fixed-term training positions which allow them to complete either their doctoral degrees or their *Habilitation*. The crucial difference to the tenure track is that successful completion of the training phase does not guarantee a permanent position.

Although there are structural similarities between those undergoing either a period to complete the *Habilitation* or as a tenure track professor (e.g., a period of extension beyond the doctorate; undergoing another level of peer scrutiny through examination in the case of the former or assessment of the tenure file in the case of the latter; the right to teach independently (*venia legendi*)), there are several key differences. In the *Habilitation* system, the training period, called the 'qualification agreement,' does not guarantee employment. The 'assistant' literally assists her or his professor. Tenure track assistant professors do not require a training period. Although their research, teaching, and service skills improve with time and experience, they are expected to perform their duties independently, often with advice and support of senior colleagues, but not under their thumbs. Fixed-term contracts are also granted for special projects that have a beginning and an end. Researchers employed in such projects are usually hired on 'soft money'; that is, funds outside of the regular general operating funds of the university (e.g., a research grant). In order to increase competitiveness, some European countries have strongly amplified this type of research by shifting financial resources from general university funds to the granting agencies; this practice is criticized by Münch (2011). Hence, the peer review process ensures that only 'excellent' researchers are successful in these competitions. As a result, the number of fixed-term postdoctoral positions has escalated.

To what degree such types of employment carry the risk of precarious positions depends on a variety of factors. The element of time is crucial. For doctoral students, fixed-term employment in research projects provides welcome opportunities to gain practical experience in research. The same is the rule for postdoctoral fellows, granted that there is a realistic opportunity for them to embark on regular – that is, tenure track – career trajectories or other forms of permanent employment. However, in this type of employment arrangement, the later stage researcher is at much greater risk in terms of job security. Another critical factor is the legal possibility to continue in renewable fixed-term projects over the long term. In some countries, unions have been successful at legally banning a succession of fixed-term contracts, labeled 'chain

contracts,' that exceed a given number of years. The intention of the unions was to reduce risk for employees by forcing employers to convert fixed-term positions into permanent ones. However, contrary to what was intended, in many European universities systems, rather than strengthening the job security of researchers, this policy has made these positions more vulnerable. Universities either cannot afford or are not willing to give researchers hired to work on specific projects permanent positions. Nor are they legally allowed to renew contracts after a specified number of years. The term *Prekariat* in German and *précariat* in French, defined as a social group that suffers multiple forms of insecurity, has emerged and has triggered debate about the increase of such positions and their associated dangers.

Hierarchies

Academic systems are highly stratified with respect to reputation, salaries, and the working conditions of academics. In the past, small elite systems that had preceded massification of higher education were indeed stratified. However, subsequent expansion has increased the functional differentiation of academic work significantly, and as a result has increased the degree of stratification. During the late nineteenth and early twentieth centuries, most higher education systems adopted, in one way or another, the Humboldtian ideal of unity of teaching and research (although as Kezar (2013) rightly points out, historically the academic profession has been one of continuous change). Massification of higher education, commencing in the second half of the twentieth century, has partly reversed this trend by creating sectors and segments that are devoted primarily to teaching (e.g., the community college sector in North America, the former polytechnics in UK, and *Fachhochschulen* in Germany). The research function is the most important criterion for the stratification of reputation, income, and working conditions. Typically, research universities have higher reputations than teaching institutions. However, some countries have elite teaching sectors, such as the private liberal arts colleges in the United States or the *grand écoles* in France. The former are undergraduate institutions and the latter are professional specialized schools that constitute the elite segment of higher education and have a more esteemed reputation than research universities in France.

Mass higher education systems of today embody different kinds of functional differentiation and reputational stratification. As a rule, national systems that are strongly steered by governmental intervention are differentiated into different sectors. In such systems, reputation, salaries, and working conditions are usually quite different among sectors; however, within each sector, little stratification exists. In most European countries, public research universities are treated equally by governments, irrespective of informal reputational hierarchies (as expressed in rankings). As such, working conditions for academics in each of the sectors are fairly equitable. In countries with more market-oriented systems such as the UK or the United States, the research university sector is highly stratified in terms of, for example, reputation, wealth, faculty access to resources, working conditions, and composition of the student body. Stratification among universities in the United States has greatly intensified over the last 30 years (Geiger, 2010). This shift is evident by the emergence of 'elite clubs' such as the Russell Group in the UK and the 'Big Five' in Canada.

University systems that are divided into sectors have little institutional differentiation within each sector. However, within each institution, the hierarchy between the different academic status groups, between full professors and nonprofessorial staff, between senior and junior academics, is strongly pronounced. In other words, academia in such countries is divided in a national guild of senior academics (with little differentiation among institutions) and various types of nonprofessorial groups. Status differences appear within every institution, with working conditions for each status group fairly equal within each sector. Conversely, status hierarchies in market-oriented systems within each university are comparatively flat; however, status differences between different institutions are strongly pronounced. Depending on the perspective, these patterns in one system may be regarded as more egalitarian than another. Some observers regard European higher education systems as less hierarchical than US higher education because institutional stratification is much more flat. Others claim that the North American pattern is more egalitarian because the hierarchy between senior and junior academics is much less vertically stratified. In fact, hierarchies are strongly pronounced in both academic worlds, albeit in qualitatively different forms.

International data on academic salaries are rare and problematic in terms of comparability. The United States compiles extensive databases at the national level; however, the way that data are aggregated does not reflect substantive wage differentials. The Academic Career Observatory of the European University Institute in Florence (http://www.eui.eu/ProgrammesAndFellowships/AcademicCareersObservatory/CareerComparisons/SalaryComparisons.aspx) provides salary comparisons for selected countries. A study by the European Commission (2007) has attempted to adjust academic salaries to the cost of living of the respective countries. Also, salary progression by experience and gender is provided. An attempt to broaden comparisons beyond OECD countries has been conducted by Philip Altbach et al. (2012).

The Case for and against Tenure

The most common perspectives used to frame the discussion in support of tenure are either that of academic freedom or economics of tenure.

Academic Freedom Perspective

Historically, the hiring of professors was haphazard with little specificity in contracts regarding terms of the employment. Faculty had 'tenure during pleasure' which meant the pleasure of the university board and faculty members could be fired without cause. As early as 1915, the American Association of University Professors (AAUP) addressed the issue of tenure (Metzger, 1987: 167). Following a spate of dismissals and related legal challenges, in 1940 the AAUP produced a document entitled *Statement of Principles on Academic Freedom and Tenure* which stated,

> academic freedom is essential to these purposes and applies to both teaching and research. Freedom in research is fundamental to the advancement of truth. Academic freedom in its teaching aspect is fundamental for the protection of the rights of the teacher in teaching and of the student to freedom in learning. It carries with it duties correlative with rights. Tenure is a means to certain ends; specifically: (1) freedom of teaching and research and of extramural activities, and (2) a sufficient degree of economic security to make the profession attractive to men and women of ability. Freedom and economic security, hence, tenure, are indispensable to the success of an institution in fulfilling its obligations to its students and to society.
>
> American Association of University Professors, 1970

Scholars such as Christopher Jencks and David Riesman (1968) celebrated "the rise to power of the academic profession" (p. xiii) because tenure harnessed the unfettered power of administrators. Academic freedom is a central tenet of tenure (Brown and Kurland, 1990).

Economics of Tenure Perspective

The long-held view is that tenure is appropriate for the type of work for which academics are trained and in which they engage. Preparation for such a career is highly specialized and requires years of training; hence, possibilities for transferring these skill sets are limited. Without tenure, it would be difficult to entice highly talented young people to devote extensive time and financial resources on careers that are considered as high risk (McPherson and Winston, 1988). In addition, without a tenure system, a newly hired faculty member could be perceived to pose a considerable threat to the positions of existing faculty members. Since hiring in academia is unlike other careers because it entails a strong peer review component, in the absence of tenure, faculty may be more inclined to hire less dangerous and hence more mediocre junior colleagues (Carmichael, 1988).

In the 1980s, the concept of tenure was besieged (Chait and Ford, 1982; Finkin, 1996; Horn, 1999a,b). Arguments fueling the debate against tenure included the following: Because it was difficult to terminate nonproductive professors, it promoted the promulgation of 'deadwood' within academic departments. Also, because of particular departmental cultures, tenure was alleged to inhibit, rather than promote, creativity. Also, it was argued that universities were paralyzed by a rigid – rather than flexible – academic labor force. The key counterargument supporting tenure systems was that a better substitute did not exist. Renewable contracts were costly in terms of resources that would not offset the 'deadwood' problem. Also, because tenure goes hand in hand with academic freedom, tenure protects outspoken and intellectually innovative faculty. Over the last three decades, these debates continue (Acker, 2009; Finn, 2009; Horn, 2009; Kingwell, 2009; Soto Anthony and Hayden, 2009). Such attacks have served as ideological support for shrinking of the stock of tenured professors based on economic grounds.

Current Reforms and Policy Debates

Over the last three decades, significant changes have taken place in regard to the structure of academic careers. With tremendous expansion of higher education – in Martin Trow's (1999) terminology, from elite (less than 15%) to mass (i.e., up to 40%) to universal participation (greater than 40%) – concurrently the nature of the academic labor force has been restructured. In most countries, academic posts in higher education and research systems continue to grow (as expansion of higher education has reached unprecedented levels); however, the composition of the academic workforce is undergoing transformation. The balance between permanent and fixed-term positions is shifting toward the latter. The academic core of tenured professors is declining in most OECD countries, not necessarily in absolute numbers, but as a percentage of the total academic workforce (Kezar, 2013; Schuster and Finkelstein, 2006).

In different countries, this general trend is evolving in various ways. On one extreme, the American system has the highest percentage of permanent positions; on the other extreme, in the German system only 10% of the entire academic workforce has permanent positions (Kreckel and Zimmermann, 2014). All others have fixed-term positions in the form of 'professors in waiting' or those who work from contract to contract (soft money) for their entire careers without any guarantee of renewal. The contraction of a highly developed system (e.g., the United States) in order to reorient itself to higher education expansion in the twentieth century is in stark contrast to an ineffective response of an outdated elite system (e.g., Germany) – characterized by escalation of the 'risk' character of academic careers and related dead ends. However, increasing awareness of the challenges facing such systems has led some universities to introduce bold reforms. For example, the Technical University of Munich has introduced a tenure track system (München, 2012).

Ongoing contraction of tenured positions in both systems has severe implications for the career prospects of junior academics and graduate students who are considering academic careers. Because the prospect of embarking on a secure academic position is decreasing, the next generation of prospective academics faces the risk of precarious employment. Two recent reports address this issue (Boston University, 2010; The Modern Language Association of America, 2014).

Currently, two phenomena can be observed. On the one hand, an increasing proportion of teaching duties in higher education systems is carried out by fixed-term and mostly part-time academics, such as adjunct professors in the United States or *Lektoren* in the German-speaking countries. On the other hand, academic research is becoming increasingly project based and is mostly performed by postdoctoral fellows (sometimes doctoral students) who are employed on soft money. Increasingly, these positions are funded by agencies that fund basic research and/or from private contractors.

Both developments point toward fundamental shifts in the normative underpinnings of the academic career structure. Since the Humboldtian reforms in Prussia approximately 200 years ago, the norm for the academic core position has been the combination of teaching and research, mostly supplemented by other duties such as administration or service. This strong teaching/research nexus was tailored originally for elite higher education institutions of the nineteenth century; however, it has been maintained and adapted during the period of transformation from elite to mass higher education. In that course of

massification, such a strong emphasis on both research and teaching has been questioned regarding its appropriateness for the changing nature of higher education. However, the normative power of this model has been forceful enough to keep the traditional academic job description intact. As higher education systems surpass massification and move toward universal participation, the unconditional research/teaching nexus shows signs of erosion. The high cost of the traditional academic model that is increasingly at odds with a more and more diversified system of research and higher learning is the main driver of change. Academic careers that are defined by a strong emphasis on both research and teaching will continue to exist, but most likely the proportion of faculty who hold such positions will be reduced to minority status in academia. This raises the question of how the decoupling of this traditional structure will affect the academic profession in general. Currently, it goes hand in hand with a decrease in permanent positions and an intensified risk of precarious positions for future generations of academics.

Other parallel structures of full-time employment are either developing or under consideration in various jurisdictions. Teaching tenure track positions are emerging to meet the demand for more instructional time which is currently met increasingly through contingent teaching staff (e.g., see the University of British Columbia). Renewable full-time contracts for sessional or adjunct faculty, as specified in university collective agreements, have the potential to provide a higher level of job security and benefits for those who would otherwise face precarious labor market conditions. However, precarious academic appointments, defined by lack of job security, low pay, few or no benefits, poor working conditions, and limited job security remain common in the academic institutions of today (Kezar, 2013).

Academia has always been a 'risk career' (Weber, 1947); however, recent developments are dangerous in that the most talented graduates are increasingly less attracted to this profession. High on the agenda are policy solutions that do justice to the increased diversification of the academic landscape while providing stable career options to future teachers and researchers.

Abstract

Engagement is a 'metaconstruct' that includes behavioral, emotional, and cognitive engagement. The research on engagement has grown out of two theoretical traditions including research on school dropouts and research grounded in motivational and psychological theory. Engagement has been shown to be a key contributor of academic achievement, school completion rates, and lower risk behaviors. Prior research has linked family factors and instructional and social dimensions to higher engagement. Methodological advances in research include: (1) conceptualizing engagement as a multidimensional construct, (2) examining developmental trajectories of engagement, (3) testing reciprocal relations between context and engagement, and (4) using person-centered analyses to explore diversity of engagement profiles.

Engagement

There in a growing interest in the construct of engagement among researchers, policy makers, and practitioners. Engagement has been studied at four different nested levels, including the following: (1) engagement with prosocial activities (i.e., families, schools, and community organizations), (2) engagement with school, (3) engagement in the classroom, and (4) engagement with learning activities (Skinner and Pitzer, 2012). Engagement in school refers to involvement in academic contexts and school-based extracurricular activities, such as sports, music, and student government. Student engagement in the classroom includes aspects of curriculum and students' relationships with teachers and peers. Finally, engagement in learning activities refers to specific aspects of the task and activity structure.

An important question in the literature is how engagement differs from motivation. Although some scholars use these terms interchangeably, the majority assume that engagement and motivation are distinct but related constructs. Motivational constructs tend to emphasize individual differences and psychologist processes. In contrast, engagement reflects an individual's interaction with context. An individual is engaged in something (i.e., task, activity, relationship), and their engagement cannot be separated from the environment (Fredricks et al., 2004). Most scholars postulate that motivation is the precursor of engagement. In other words, engagement is the outward manifestations of a motivated student.

What Is Engagement?

What is school or student engagement? The answer to this question has changed over time (Appleton et al., 2008; Christenson et al., 2012; Fredricks et al., 2004). Early scholars defined engagement primarily in terms of observable behaviors such as participation or time on task. Other scholars have proposed a two-dimensional model that includes both behavioral and emotional engagement (Finn, 1989; Skinner et al., 2009). More recently, scholars have suggested a tripartite conceptualization of engagement that includes behavioral, emotional, and cognitive dimensions (Fredricks et al., 2004). Still other scholars have proposed a four-dimensional model, adding academic engagement (i.e., time on task, homework completion) or authentic engagement (i.e., proactive, intention, constructive contribution) to the two- and three-dimensional engagement models (Christenson et al., 2012).

Behavioral engagement has been defined in several ways including the following: (1) positive conduct and absence of disruptive behavior, (2) participation in classroom learning and academic tasks, and (3) participation in school-based extracurricular activities. Emotional engagement has been defined in terms of students' positive and negative reactions, including interest, boredom, happiness, sadness, and anxiety. Other scholars have defined emotional engagement as value and school belonging. Finally, cognitive engagement has been defined as the use of self-regulatory strategies, investment in learning, depth of processing, and preference for challenge (Fredricks and McColskey, 2012).

One commonality across the recent conceptualizations of engagement is that it is a multidimensional construct. However, there is less agreement on the number and types of engagement, which range from two (i.e., behavior and emotion) to four (i.e., academic, behavioral, cognitive, and psychological/affective). In addition, there has been considerable variation in how each subtype is defined and operationalized for measurement purposes. There is also variability in the location and time frame of engagement. For example, scholars differ in whether they focus on engagement at the school or at the classroom level, and whether they focus on moment-to-moment task engagement or longer term engagement. Scholars also differ in whether they view engagement on a single continuum ranging from high to low, or whether engagement and disengagement (i.e., disaffection) are considered distinct and separate constructs (Skinner et al., 2009). Finally, there is a debate about whether it is important to distinguish between facilitators of engagement, or explanatory casual factors such as teacher support, from indicators, or descriptive markers of engagement, such as effort, attention, and interest, in both definitions and measures of engagement (Appleton et al., 2008).

Measurement of Engagement

This past decade has also seen increasing attention to the measurement of this construct.

The most common way to measure engagement is with student self-report measures. This assessment technique is particularly useful for assessing emotional and cognitive engagement which are not directly observable and need to be inferred from behavior. In a recent review of the literature, Fredricks and McColskey (2012) identified 12 self-report survey measures that have been developed to assess engagement, with varying quality of psychometric properties. These measures differed in the types of engagement assessed and whether they were designed to measure school engagement generally or within a specific academic subject area. The majority of these self-report measures assessed general school engagement. One problem with general measures of engagement is that it is difficult to determine the extent to which engagement represents a general tendency and the extent to which it is situation specific.

Another way to measure student engagement is with observational methods. The majority of these observational measures assess on-task behaviors as an indicator of behavioral engagement. These measures use a form of time sampling, in which an observer records whether a predetermined category of behavior is present or absent during a specific time period. One problem with these observational measures is that they provided limited information on the quality of effort, participation, or thinking (Fredricks et al., 2004). For example, some students who are judged to be on-task by observers may not be cognitively engaged, while students who appear to be off-task may actually be deeply thinking about the task.

Why Does Engagement Matter?

There has been an explosion of research on engagement over the past two decades. Why? First, engagement is a key contributor to academic performance. Several studies have linked engagement in school and out-of-school extracurricular activities to higher grades, achievement test scores, school completion, and graduation rates (see Fredricks et al., 2004; Fredricks and Eccles, 2006). Engagement is also correlated with lower delinquency, substance use, depression, and dropout rates (Li and Lerner, 2011). Second, the ideas of engagement and disengagement are easily understood by educators. Many teachers report that disengagement is one of the biggest challenges they encounter in their classrooms. Recent studies indicate that as many as 40–60% of students are showing signs of disengagement (Yazzie-Mintz and McCormick, 2012).

Third engagement is presumed to be malleable and can be influenced by social and instructional factors. In fact, increasing engagement has been the central goal of many school improvement efforts, especially at the secondary level (National Research Council and Institute of Medicine, 2004). Focusing on student and school engagement as an explanatory variable for achievement, deep learning, and school completion offers more insight into intervention and prevention strategies than focusing on unalterable demographic variables like gender, ethnicity, and socioeconomic status. Finally, engagement has intuitive appeal because it is assumed to be a metaconstruct that has the potential to provide a richer characterization of how students' think, act, and feel, than research on any single component can offer. Considering engagement as a multidimensional construct also can provide more specific prescriptions for intervention and prevention efforts.

Theoretical Frameworks – Dropout Literature

Research on engagement has grown out of two separate literature that draw on different theoretical traditions including: (1) research on school dropouts and (2) research grounded in psychological and motivational theory. For example, the participation–identification model (Finn, 1989) is a seminal theory addressing the critical role of school engagement in the process of dropout and school completion. In this two-component model, participation refers to behaviors that engage students in learning (i.e., behavioral engagement), and identification refers to students' feelings of belonging and valuing (i.e., emotional engagement). According to this model, dropping out of school is the result of a long-term developmental process that occurs when students fail to participate in learning activities and fail to identify with school. Prior research supports the assumption that dropout and school completion rates can be predicted from behavioral indicators and attachment to school (Christenson et al., 2012).

The life course perspective is another theoretical model that comes out of the dropout literature. This theoretical perspective views dropping out of school as a process of academic disengagement that can be traced back to student's earliest experiences in school (Alexander et al., 2001). A few longitudinal studies have used a life course perspective to track the long-term educational experiences of low-income children. This research supports the assumption that developmental pathways to school dropout and completion begin with the engagement behaviors and engagement attitudes developed during the early school years.

Theoretical Frameworks – Motivational and Developmental Literature

Much of the research in this field has applied motivational and developmental theories to research on student engagement. For example, one prominent theory guiding the current literature is the self-system motivational model. This mediational model is rooted in self-determination theory and links contextual factors (i.e., classroom structure, autonomy support, and involvement) to patterns of engagement (i.e., engagement vs. disengagement), through self-system processes, or an individual's appraisals of how *competent*, *autonomous*, and *related* he or she feels within particular contexts (Connell and Wellborn, 1991). This model assumes that a supportive classroom, peer, or family context (i.e., optimal structure, autonomy support, and high involvement) promotes positive self-perceptions, which in turn, increases behavioral, emotional, and cognitive engagement. Conversely, a less supportive classroom, peer, or family context undermines self-perceptions which in turn, results in disengagement. There is growing body of literature supporting the links between contextual factors, self-system processes, and behavioral, emotional, and cognitive engagement (Skinner and Pitzer, 2012).

The person–environment perspective (Eccles and Roeser, 2009) is another relevant theoretical model. According to a person–environment fit model, behavior and motivation are influenced by the fit between characteristics individuals bring to their social environments and the characteristics of the social environment. Eccles and her colleagues have used this theory to explain the decline in motivation and engagement during the middle school years, suggesting that there is a mismatch between adolescents' developmental needs and the environment of middle schools. Person–environment fit models could also help to explain the continuity and/or discontinuity between the values and practices espoused by families and schools to support engagement. One explanation for the disengagement that some students experience in schools is a discontinuity between their school and home environments in terms of support and expectations for learning.

Finally, other scholars have used a bioecological model as the overarching theoretical model for studying engagement (Bronfenbrenner and Morris, 2006). This model focuses on four contributors to development, including *person*, *process*, *context*, and *time*. This theoretical model recognizes both the individual characteristics, such as ability, socioeconomic status, and performance, and the contextual factors, such as the home, school, neighborhood, and larger sociocultural context, that impact on engagement.

Classroom Context and Engagement

Teacher and Peer Support

Teacher support in terms of caring, involvement, and encouragement has been linked to indicators of behavioral, emotional, and cognitive engagement across race, ethnicity, and class (Fredricks et al., 2004). A close supportive relationship with a teacher is especially important for students who are academically at risk and showing signs of disengagement. Peer support for learning and the quality of friendships are also linked to behavioral and emotional engagement (Christenson et al., 2012; Kindermann, 2007).

Task Characteristics

The type of academic tasks students do in school is another important determinant of engagement. Many students disengage from learning in school because the classroom tasks are boring and offer limited opportunities for deeper conceptual understanding. Researchers are exploring how to make classroom tasks more intrinsically motivating, interesting, and cognitively engaging to students. Engagement is higher in classrooms with authentic tasks that are situated in meaningful contexts, are cognitively complex, and reflect how learning happens outside of the classroom (Fredricks et al., 2004). The degree of autonomy support, or the amount of freedom a student is given to determine his or her behavior, also influences classroom engagement (see Eccles and Roeser, 2009). For example, autonomy supportive instruction (giving choices, making learning relevant) predicts higher classroom engagement (Reeve et al., 2004).

Classroom Management/Structure

There is a positive relationship between being in a well-managed classroom and exhibiting behavioral engagement as measured through time on task (Fredricks et al., 2004). Both behavioral and emotional engagement are also enhanced in classrooms where teachers establish procedures that help to monitor student progress, ensure work completion, provide adequate structure, and facilitate productive group functioning.

Family Context and Engagement

Parents influence children's engagement through the types of home environments they create, the values they endorse, and the experiences they provide. Prior research has linked parental expectations, parental involvement, and parental social support to indicators of behavioral, emotional, and cognitive engagement (Eccles, 2007; Wang and Eccles, 2012a). Parents also impact on student engagement through their extent of autonomy support, or the degree to which they encourage their children to initiate their own behavior, take an active role in solving their own problems, and express their points of view. For example, strong parental autonomy support predicts behavioral engagement (i.e., time on homework, lower deviance), emotional engagement (i.e., intrinsic motivation, positive attitudes toward school), and cognitive engagement (i.e., persistence in the face of challenge) (Pomerantz et al., 2007).

Engagement as a Multidimensional Construct

In 2004, Fredricks and her colleagues outlined several limitations with the literature on engagement to date. Over the past decade, there is a growing body of research addressing these critiques. One of the central concerns articulated in the 2004 review is that scholars had failed to capitalize on the potential of engagement as a multidimensional construct. Prior to 2004, much of the research had either combined conceptually different engagement measures into one index or focused on only one of components of engagement, usually behavioral engagement. In the last decade, a growing number of scholars have conceptualized engagement as a multidimensional construct. The majority of this research defines engagement in terms of behavioral, emotional, and cognitive dimensions. However, there is still significantly more research on behavioral engagement than the other two dimensions.

Another critique was that few studies used a multidimensional perspective to disentangle differences in the antecedents and consequences of engagement by type of engagement. This critique has been addressed in a few recent studies. For example, Wang and Eccles (2012a) found that the association between social support and engagement differed across the three types of engagement. Other research has shown that the three types of engagement have differential relations to developmental outcomes (Archambault et al., 2009; Wang and Eccles, 2012b). For example, Archambault et al. (2009) found that a measure of global disengagement was associated with dropping out of school. However, when broken into subcomponents, only behavioral engagement predicted school dropout.

Trajectories of Engagement

Another criticism articulated in the 2004 review was the over-reliance on cross-sectional and short-term longitudinal studies. Recently, a few studies have addressed this critique by using longitudinal modeling techniques to chart changes in engagement over longer periods of time. This research shows declines in student engagement during the high school years (Van de gaer et al., 2009; Wang and Eccles, 2012b). In addition, a few studies have used longitudinal modeling techniques to explore the heterogeneity in engagement trajectories during the early grades (Ladd and Dinella, 2009) and during the adolescent years (Archambault et al., 2009, 2008; Li and Lerner, 2011). These studies show diversity in pathways of behavioral, emotional, and cognitive engagement over time. For example, Li and Lerner (2011) identified four engagement trajectories: (1) high stability, (2) moderate stability, (3) transitory decreasing, and (4) decreasing. In turn, these trajectories were linked to different patterns of academic achievement, psychological adjustment, and risk behavior.

Although these longitudinal studies have provided a more nuanced portrait of developmental changes in school engagement, there is still a need for research that examines the trajectories of engagement at different stages of development, particularly through changing school contexts and developmental transitions. In addition, there is a need for research that examines the individual and contextual factors that may help to explain both continuity and change in engagement trajectories. Such research will provide insights into the risk and protective factors associated with the development of each type of engagement. Finally, it is important to further examine the relation between different types of engagement trajectories and student outcomes over time to better understand what are the most adaptive and risky profiles.

Reciprocal Relations

Although most theories assume a reciprocal relation between context and engagement, the majority of research has been based on correlational and cross-sectional studies. This research tends to be interpreted as reflecting context effects on engagement. A few survey studies have tested bidirectional relations between contextual factors and engagement. These studies show that adults respond differently to children depending on their level of engagement or disruptive behavior, and that children are allowed entry into peer groups based on their engagement in school (Kindermann, 2007; Skinner and Pitzer, 2012). This initial research suggests that these bidirectional relations are self-amplifying and magnify initial differences in engagement over time. Higher engaged students get more positive support, while less engaged youth experience less supportive and positive interactions over time.

Although the research has become more methodologically sophisticated over the past decade, there is clearly a need for further longitudinal research that tests the cyclical associations between contextual factors, engagement, and developmental outcomes. Incorporating other measurement techniques may also help scholars of engagement to measure cyclical processes. For example, several measurement techniques have been developed in the self-regulated literature to evaluate students' engagement in the context of specific learning tasks. These measures include: (1) behavioral traces (i.e., overt indicators of student cognition during tasks), (2) direct observations of student behavior, (3) think aloud protocols, and (4) self-regulated learning (SRL) microanalysis (i.e., structured interview of students' attitudes and cognitions before, during, and after a task) (Cleary and Zimmerman, 2012).

Person-Centered Approaches

The vast majority of research on student engagement has used variable-centered techniques to isolate the average relations between contextual factors, engagement, and other developmental outcomes. A complementary approach is to use person-centered techniques to capture patterns of engagement within individuals across time or contexts. These techniques can help to answer questions about how much individuals vary in terms of their behavioral, emotional, and cognitive engagement profiles and whether these different profiles have different implications for individual developmental processes. Failure to consider the diversity of within-person profiles impedes our ability to design targeted intervention for specific groups of students.

A few studies have used person-centered approaches to identify different patterns of student engagement (Janosz et al., 2000; Wang and Peck, 2013). This research has shown that there are different profiles of behavioral, emotional, and cognitive engagement. For example, Wang and Peck (2013) identified five different profiles: highly engaged, moderately engaged, minimally engaged, emotionally disengaged, and cognitively disengaged. These five profiles differed on indicators of educational and psychological functioning. Recently, a few studies have combined person-centered and longitudinal approaches to understand variability in engagement profiles over time (Archambault et al., 2009; Ladd and Dinella, 2009; Li and Lerner, 2011).

Conclusion and Future Directions

Important methodological and theoretical advances have led to increased knowledge about engagement, though it is clear that several gaps in the literature still remain. Part of the appeal of engagement as a construct is that it is multidimensional and comprised of observable behaviors, internal cognitions, and emotions. This makes it a relevant construct in a variety of research areas and appeals to both policy makers and practitioners. However, one problem with engagement being a broad 'metaconstruct' is that it has resulted in considerable variability in definitions both within and across the different types of engagement. In other words, one author's conceptualization of behavioral engagement can be and often is the same as another's operationalization of cognitive engagement (Christenson et al., 2012). For example, value has been classified as an aspect of both emotional and cognitive engagement. Additionally, effort has been used by some to describe compliance with work requirements (behavioral engagement), and by others to reflect the degree of psychological investment

in learning (cognitive engagement) (Fredricks and McColskey, 2012).

One concern is that engagement is being used so broadly that it appears to explain everything related to students' experience and success in school. Although this broad generality has utility in discussions related to policy and practice, it is more problematic in research that is attempting to examine specific hypotheses about the relation between context and engagement. This lack of definitional clarity has also made it difficult to compare findings across studies. Another concern is that definitions of engagement overlap with other educational constructs such as self-regulation, school bonding, belonging, and school climate, which often have much stronger bodies of literature supporting the construct. Researchers need to be clearer about how they are defining engagement, at which level they are measuring, and the 'value added' from studying engagement as opposed to these earlier literature (Fredricks et al., 2004).

Although there is a growing consensus that engagement is a multidimensional construct, we know much less about the extent to which emotional, cognitive, and behavioral engagement have separate and cumulative effects on achievement outcomes, school completion rates, psychological functioning, and risk behaviors, as well as the potential mediational processes involved (Christenson et al., 2012). Another important question is how the different types of engagement influence each other. Theoretical and empirical relations between the three types of engagement are lacking. One example is the participation–identification model, which assumes that behavioral engagement (participation) leads to emotional engagement (identification), which in turn increases behavior (Finn, 1989). Longitudinal research can help to verify the tenets of this model and how the different dimensions are associated with each other.

In addition to definitional challenges, there is a critical need for better measures of student engagement. One problem is that scholars often do not have a strong theoretical or conceptual framework guiding the choice of indicators. Several scholars have argued that a more systematic and thoughtful attention to the measurement of student engagement is one of the most pressing imperatives for future research (Appleton et al., 2008; Fredricks and McColskey, 2012). It is clear that we cannot know if we are improving engagement unless we are able to measure it accurately.

As outlined in Fredricks and McColskey's review (2012), the number of self-report surveys developed to assess engagement has increased dramatically over the past decade. However, the extent of psychometric support for these measures varied dramatically. In addition to self-report instruments, there is need to consider measurement from additional perspectives (i.e., teacher and parent). It is also important to incorporate multiple methods (i.e., qualitative and quantitative) and assess engagement at multiple levels (i.e., school, class, and moment to moment) (Christenson et al., 2012). For example, experience sampling method (ESM) is one innovative method that allows researchers to collect detailed data on engagement in the moment rather than retrospectively. In this methodology, individuals respond to periodic ESM signals with a series of questions about their location, activities, and cognitive and affective responses. Finally, it is important to examine group differences in the measurement of engagement by age, race, ethnicity, culture, and gender. This research can help to determine the extent to which the construct of engagement is universal and the extent to which it varies across demographic factors (e.g., age, gender, ethnicity, culture).

One of the strengths of engagement as a construct is that it is malleable and thus offers insight into contextual factors that can be targeted for interventions. Unfortunately, much of the prior research has made it difficult to test questions of malleability (Fredricks et al., 2004). There is a critical need for research that goes beyond descriptive and correlational studies to determine which aspects of context influence engagement over time. There is also a dearth of intervention studies which examine the efficacy of different interventions in increasing engagement.

Finally, the range of participants in engagement studies needs to be expanded to account for variation in students' backgrounds and experiences. In addition, there is a need for research testing whether contextual factors have a differential effect on engagement across different demographic groups. For example, some research suggests that supportive relationships with teachers may have a greater effect on engagement for minority students and for girls than for Caucasian students and boys (Christenson et al., 2012). Person–environment fit is one theoretical model that can be used to examine the types of contexts that are most effective in increasing engagement for particular types of students. This information can help to develop targeted interventions that are specific to different groups of students.

Academic Motivation and Performance: Task Value Interventions

Yoi Tibbetts, Elizabeth A Canning, and Judith M Harackiewicz, University of Wisconsin–Madison, Madison, WI, USA

Abstract

We review interventions that promote motivation in academic contexts. A variety of interventions have been used to enhance subjective task utility – the belief that a task is relevant to other activities or personal goals, with positive implications for interest and performance. We focus on experimental field studies in high school science and college psychology classes. We also review a randomized intervention in which parents received information about the utility value of math and science for their teens in high school; this intervention led students to take nearly one semester more of science and mathematics, compared with the control group. We discuss the mechanisms through which these interventions work.

What students learn in school does not always appear to have relevance to their own lives. When students encounter subjects that appear to have minimal practical use, they may find themselves disengaged, lacking the motivation that educators and parents strive to inspire. This same apathy may be the cause of a number of disturbing academic trends, including reduced interest in math and science over time (Hidi and Harackiewicz, 2000) as well as marked declines in students' pursuit of STEM (science, technology, engineering, and math) majors when compared to other academic fields (National Center for Education Statistics (NCES), 2011). However, researchers have recently begun to develop interventions that may address these motivational problems by increasing student interest in academic disciplines. Some researchers have tried to promote interest by varying features of academic tasks (Bergin, 1999; Hidi and Baird, 1988; Lepper and Henderlong, 2000), others have tried to influence students' sense of autonomy and competence (Deci and Ryan, 1985; Harter, 1981), and others have worked to change individuals' perceptions of tasks (Harackiewicz and Hulleman, 2010; Wigfield and Cambria, 2010). Because interest is a powerful predictor of important achievement choices such as future course enrollment and choice of major (Harackiewicz et al., 2002) as well as various academic performance outcomes (Ainley et al., 2002; Schiefele, 1991), interventions that prove successful in promoting interest in academic topics represent meaningful strides toward a better educated society.

Interventions designed to promote interest can take many approaches. For example, a teacher might try to make an academic task more interesting by changing features of the task, assigning group projects, or embedding learning activities in games. However, it is not always possible to change the nature of a task or activity. A parent or teacher cannot change the fundamental principles of mathematics or science, but they may be able to change the way students think about these subjects. For example, a parent might be able to promote interest in an academic topic by relating it to their child's recreational interests or career goals. By changing the perception of the activity (i.e., helping students perceive tasks as personally important), it may be possible to influence interest. With various possibilities for influencing student interest, it is important to distinguish interventions that change the structure of an activity (Lepper and Cordova, 1992; Schraw and Dennison, 1994) from those that change an individual's perceptions of an activity (Iyengar and Lepper, 1999). Task-based interventions typically vary collative variables (e.g., complexity, incongruity, novelty, variability) to stimulate attention, arousal, and task engagement (Berlyne, 1960), whereas task-value interventions focus on individuals' perceptions and development of subjective task values (Harackiewicz and Hulleman, 2010), guided by Eccles' expectancy-value model (Eccles et al., 1983).

Expectancy-Value Model

According to this model, perceived expectancies for success and subjective *task values* both determine motivation and performance on achievement tasks. One way to inspire interest and motivation is to increase the perceived expectancy of success, and a large research literature has examined the role of self-efficacy and performance expectations in promoting interest and performance (Harter, 2006; Pajares, 1996). It can be difficult to intervene with respect to students' performance expectations, however, and in this article, we concentrate on interventions focused around task values.

Indeed, it may prove more feasible to influence students' subjective task values for academic tasks. Eccles (Eccles, 2009; Eccles et al., 1983) argued that it is important to consider how individuals perceive and value a task, and identified four subjective task values: *intrinsic value* – the perceived importance of a task because of its inherent enjoyment; *attainment value* – the perceived importance of a task for an individual's identity and self-worth; *utility value* – the perceived importance of a task for accomplishing future goals, relevant to an individual's life; and *cost value* – the negative aspects of engaging in a task (e.g., time consumption, performance anxiety). Her expectancy-value model posits that an increase in intrinsic, attainment, or utility value will lead to greater motivation toward an academic task. Conversely, if these perceived task values decrease, individuals may be less likely to pursue the task.

Of the four task values, Eccles and colleagues consider utility value to be the most 'extrinsic' because it extends beyond the task itself to connections between that task and other tasks, activities, or goals (Wigfield and Eccles, 1992). A person finds utility value in a task if they believe it is useful and relevant

beyond the immediate situation, for other tasks or aspects of a person's life. It involves learning the content as it applies to oneself or real life, rather than learning the content absent any personal applicability. For example, when students encounter plant genetics in their biology class, the content may not seem immediately valuable or applicable to their lives. Learning about DNA methylation and gene coding in plants may not seem to have obvious practical or personal implications. However, if a health-conscious student perceives a connection between what they are learning and how it can enable them to distinguish genetically modified food from organic food at grocery stores, they may become more vested in biology and engage more with the content. These types of external connections to content distinguish utility value from the other more internally regulated task values.

Whereas intrinsic and attainment value are based on the inherent enjoyment of the task itself and the importance of the task for an individual's identity, respectively, utility value is predicated on perceiving connections between the immediate task and a future task or activity. Accordingly, some researchers have claimed that utility value is more 'externally regulated' than other task values (Simons et al., 2004). Extrinsic factors (e.g., rewards, prizes, competitions) have historically been at the heart of controversy in the motivation literature with many researchers arguing against the use of using external motivation to promote task motivation (Harackiewicz, 1979; Lepper et al., 1973). In fact, some of the original theorists in the achievement literature have argued that extrinsic motivation is antithetical to the development of interest (Deci and Ryan, 1985) with particularly deleterious effects for interesting activities (Deci et al., 1999). However, when an individual perceives utility value in a task, they may connect the task to important personal goals and outcomes in an intrinsically regulated way that promotes the development of interest (Vansteenkiste et al., 2006). Thus utility value may have a more positive potential than originally thought.

Moreover, given that utility value is based on perceptions of the usefulness of a task for other goals and applications, it may prove to be the task value most amenable to external intervention. A teacher or parent can point out possible connections, or help students appreciate the importance of a topic for their future goals. For this reason, recent research has examined the effects of perceived utility value within laboratory and classroom settings and focused on developing interventions that promote the perception of utility value. In order to explore how changes in perceived utility value impact interest, however, it is important to understand how interest develops over time, as well as distinguish interventions that trigger the development of interest from those that promote the maintenance or deepening of interest (Hidi and Harackiewicz, 2000).

Interest Theory

Hidi and Renninger (2006) proposed a four-phase model of interest development that charts the transition from situationally based interest to personal interest. They argue that interest is the outcome of an interaction between a person and a particular content. The potential for interest lies within the person, but the content and environment influence the strength and direction of interest as well as its continued development (Hidi and Renninger, 2006; Renninger and Hidi, 2011). The fact that interest is influenced by both content and the context of the situation suggests that interventions have the potential to both trigger interest and promote the maintenance of interest.

The two earlier phases of interest are characterized as varying degrees of 'situational interest.' In phase 1, a trigger is necessary (provided by the content or the environment) to spark a temporary affective and cognitive change that results in a short-term increase in interest. If this triggered situational interest is further supported, typically by external sources, it can develop into a more maintained situational interest (phase 2). The latter two phases of Hidi and Renninger's (2006) model are characterized by a predisposition to seek repeated engagement with the content. In order to develop emerging individual interest (phase 3) and well-maintained individual interest (phase 4), the individual must play a more active role in their interest development. Interest in the latter phases is therefore more self-generated and does not necessarily require external support to develop, suggesting that interventions may be most effective in the early stages of interest development by either aiding the development of situational interest, or promoting the transition to a more internalized interest.

In addition to describing the four phases of interest, Hidi and Renninger (2006) hypothesized that increasing the perception of the value of a task is critical for progressing from situational to individual phases of interest. An increase in the perceived value of a task serves as a motivator for individuals to continue engaging in content or an activity. Thus both the Eccles model and the Hidi and Renninger model predict that increasing perceived task value is a viable way to promote interest and motivation. With these theoretical frameworks in mind, researchers have explored the relationship between interest, motivation, and the task value most amenable to outside intervention: utility value.

Utility Value Interventions

The first studies to examine the effect of perceived utility value on educational outcomes were correlational. For example, research demonstrated that the perceived instrumentality of studying was positively correlated with students' persistence and academic performance (De Volder and Lens, 1982; Van Calster et al., 1987). Malka and Covington (2005) showed that the perceived relevance of college students' schoolwork to their future goals predicted classroom performance. A myriad of other correlational studies indicates that when students perceive value in course topics, they develop more interest, take more advanced courses in those academic disciplines, and perform better (Harackiewicz et al., 2000, 2008; Wigfield, 1994).

For example, Hulleman et al. (2008) measured perceived utility value in an introductory psychology class by asking participants to report, early in the semester, the extent to which they found class material to be useful to their everyday life and future career and then examined the relationship between perceived utility value and measures of interest and course grades. They found that perceived utility value was a significant predictor of both interest (measured at the end of the semester) and course grades. Perceptions of utility value were positively correlated with both of these important educational outcomes,

even after controlling for other important variables such as initial interest and other task values (e.g., intrinsic value).

Building on these correlational findings, Durik and Harackiewicz (2007) measured students' baseline interest in mathematics and then taught them a mental math technique in an experimental laboratory paradigm. They varied both the collative features of the task and the availability of utility value information in a crossed experimental design. They varied 'catch' features (features designed to trigger or 'catch' interest) by presenting the mental math technique with colorful fonts and pictures in the catch condition, compared to a plain black and white control condition. To vary utility value information, they provided some students with information about how the technique could be useful in everyday life (e.g., "You might use mental math to figure out tips at restaurants or to manage your bank transactions.") whereas the control condition did not present utility value information. Results indicated that the 'catch' manipulation was effective in promoting the interest of students who were low in initial interest whereas the utility value intervention increased the interest of students who were high in initial interest. Durik and Harackiewicz reasoned that situational triggers, in the form of enhanced collative features of the task, were necessary to initiate interest development for students low in initial interest, but that the utility value intervention helped high-interest participants develop a more maintained interest. Thus a task-based intervention appeared to trigger interest for low-interest participants, but the utility value intervention was effective in supporting interest for high-interest students.

Hulleman et al. (2010) also tested utility value interventions with experimental methods. In two experiments – a laboratory study and a randomized trial in a college class – utility value was manipulated through a writing intervention in which participants were asked to explain how the topic of the learning activity (math in the laboratory study and psychology in the college class) was relevant to their lives. In other words, participants in the experimental condition were asked to generate their own connections and discover utility value themselves through writing about the task. Those in the control condition wrote a summary of the material. In both experiments, the utility value intervention increased interest, especially for participants who were low in expected (laboratory study) or actual (classroom study) performance, indicating the importance of both utility value and performance expectations in predicting interest. It may be that for students who do not expect to perform well, the process of generating personal connections to an academic discipline is particularly important for triggering interest and promoting engagement in the task. Students who expect to do well may already be aware of the utility value of the activity. This possibility is supported by mediation analyses (Hulleman et al., 2010) showing that the intervention worked for low-expectancy students by promoting perceptions of utility (measured via questionnaire). In other words, the intervention increased perceptions of utility for these low-expectancy students, and perceived utility value was a positive predictor of subsequent interest in the task for all students.

Hulleman and Harackiewicz (2009) tested a similar experimental intervention with high school science students. Students enrolled in 9th-grade biology classes were randomly assigned to utility value or control writing conditions at the beginning of the semester, within classrooms. Teachers were told that the research concerned the effectiveness of writing assignments, but were blind to hypothesis and experimental condition. Students' success expectancies and initial interest in science were measured at the beginning of the semester. At the end of each unit (about every 2–3 weeks), students either wrote about how the material they were studying applied to their own lives (utility value condition) or wrote a summary of the same material (control condition). Students' interest in science and future plans for science-related careers were measured at the end of the semester, and course grades were obtained from school records. Results indicated that the intervention was particularly effective for students with low performance expectations in the class: these students reported more interest in the course topic at the end of the semester and obtained higher grades. Given that students who do not believe they can do well are especially at risk for poor performance and decreased academic interest (Eccles et al., 1983; Renninger, 2000), these are the students most in need of help. The utility value intervention improved performance for these at-risk students by nearly two-thirds of a letter grade, and promoted interest for this group. Moreover, Hulleman and Harackiewicz (2009) showed that interest predicted students' science-related career plans, suggesting that utility value interventions might have long-term effects. These results suggest that this simple intervention aimed at promoting the perception of utility value was powerful in promoting important academic outcomes.

It is interesting to note that in Durik and Harackiewicz's (2007) study in which students were presented with utility value information from an outside source, the utility value intervention was most effective for highly interested students, yet in the Hulleman studies (Hulleman et al., 2010; Hulleman and Harackiewicz, 2009), in which students generated their own utility value connections, the utility value intervention was more powerful for less confident students. This highlights the fact that learners approach tasks with different backgrounds (i.e., varying levels of interest and performance expectations) and that utility value interventions may have differing effects depending on an individual's initial orientation toward the task.

For example, the fact that externally presented utility value information (i.e., telling students why a task is important for them) was particularly effective for high-interest students in the Durik and Harackiewicz (2007) study suggests that for students who are already interested in a topic, utility value information may serve as another meaningful way to connect to content and deepen interest. In this way, utility value information may act as an additional motivator for students to continue pursuing a task. The fact that the self-generated utility value intervention in the Hulleman and Harackiewicz (2009) and Hulleman et al. (2010) study was most effective for students with low success expectancies suggests that the act of identifying personal utility value connections (i.e., writing essays about how the content is personally relevant) may be especially important for triggering interest among students who might otherwise become disengaged with the task. For these students with low success expectancies, discovering how a particular content or task relates to their life may be

a powerful mechanism for initiating the development of interest. Considered together, these results suggest that there may be different routes to the promotion of perceived utility value for students. In fact, recent research has examined the possibility of intervening with the people who likely have the greatest influence over students: their parents.

Parents: An Untapped Resource

Given the impressive potential of utility value interventions for promoting important academic outcomes, more recent research has investigated whether it is possible to influence students' perceptions of utility value in other ways. In fact, according to the expectancy-value model parents play a pivotal role in influencing their children's motivational beliefs (Jacobs and Eccles, 2000). Recent empirical work has corroborated this notion by showing that parents' beliefs in educational domains are closely linked to the beliefs and behaviors of their children, and that parental involvement is a strong predictor of student outcomes (Jodl et al., 2001; Simpkins et al., 2012). This work suggests that parents may be in a good position to influence their children's perceptions of utility for school topics.

Harackiewicz et al. (2012) tested whether it is possible to influence students' perceptions of utility value by intervening with parents in a randomized field study. Specifically, they tested whether intervening with parents could be an effective way of indirectly promoting students' perceptions of utility value, which in turn could increase mathematics and science course enrollment. This issue is particularly important in the United States where we have a disturbing trend of high school students electing not to take advanced mathematics and science courses. Only 12% of high school graduates have taken calculus, and only 29% take physics (National Science Board, 2004). Since the publication of "A Nation at Risk" in 1983 (National Commission on Excellence in Education), reinvigorating interest in STEM subjects has been part of the national agenda. Educators are worried that the increase in demand of STEM jobs in America will outweigh the supply of viable candidates; and if the United States wants to compete in a global market, it is critical that more American students pursue STEM careers (National Research Council, 2007). As recently as April 2013 the Obama administration committed $3.1 billion to improve STEM education nationwide, with $450 million being directed at boosting the number of trained educators and developing programs to inspire students to pursue STEM careers. Given all the emphasis on widening the pipeline of students who go onto STEM careers, interventions that promote STEM course-taking in high school have grown increasingly more important.

Harackiewicz et al. (2012) implemented their utility value intervention with two brochures mailed to parents and a Web site that highlighted the utility value of various STEM courses. The intervention was targeted exclusively at parents, with the hope that parents would then communicate utility value information to their teens. This represents an indirect utility value intervention in which parents were given utility value information, with encouragement to communicate that information to their teens, as well as guidance for how to do so. Participants in the randomized experiment were 188 (88 girls, 100 boys) adolescents from 108 different high schools and their parents. The first brochure, titled "Making Connections: Helping Your Teen Find Value in School," was mailed to parents of 10th grade students in October. The brochure provided information about the utility of mathematics and science in daily life and for various careers. In addition to the utility value information, the brochure included guidance for parents on how to talk to their children about connections between mathematics, science, and their children's lives.

The second brochure, titled "Making Connections: Helping Your Teen with the Choices Ahead," was sent to each parent of 11th grade students separately in January, and included a password-protected Web site titled "Choices Ahead." Similar to the first brochure, the second one emphasized the connections between mathematics and science to people's lives as well as the importance of conveying these connections to students. The second brochure was different from the first in that it placed an increased emphasis on the relevance of STEM courses for preparing students for college and future careers.

The Web site contained clickable links to a wealth of resources about STEM fields and careers in addition to interesting science sites that described the relevance of STEM topics to everyday life. The Web site also presented excerpts of interviews with current college students who highlighted the importance of their high school mathematics and science courses for their college preparation. Parents were also given the option of e-mailing specific links from the Web site to their teens. Parents in the control group did not receive either of the brochures or access to the Web site.

Self-report measures of parents' perceived utility of mathematics and science for their teens (e.g., "Math and science are important for my teen's life") were recorded at two separate points: once when the students were in 9th grade (prior to the intervention) and once when the students were in 11th grade (after the intervention materials were issued). Following 12th grade, students and parents each completed a survey assessing the extent to which parents and teens had engaged in conversations about the importance of mathematics and science, and teens provided self-reports of the perceived utility value of mathematics and science. The main hypothesis was that students whose parents had received the intervention would enroll in more advanced mathematics and science courses.

The results of this relatively simple intervention were dramatic. Harackiewicz et al. (2012) found that students whose parents were in the experimental condition enrolled in significantly more mathematics and science courses in 11th and 12th grade than their peers whose parents were in the control group. The difference was equivalent to nearly an extra semester of mathematics or science over a 2-year period. They also found, consistent with previous findings (Jodl et al., 2001; Simpkins et al., 2006), that parental education was a significant predictor of STEM course-taking in high school. The two effects were independent, and the size of the intervention effect ($\beta = 0.16$) was comparable to the effect of parental education ($\beta = 0.17$) (**Figure 1**).

Additional analyses indicated that the intervention significantly increased mothers' perceptions of STEM utility value for their teens as well as students' reports of conversations with parents about the importance of mathematics and science.

Figure 1 Number of semesters of mathematics and science courses that students took in the last 2 years of high school (as reported on their transcripts) as a function of parents' education level and experimental condition. Error bars represent ±1 Standard Error.

Thus the intervention appears to have been effective in changing parental values and in promoting conversations about the value of STEM disciplines. Process analyses elaborated on these key findings by showing that these direct effects of the intervention on mothers' perceptions of STEM utility value and students' reports of conversations about the importance of STEM were associated with indirect effects indicating that both mother values and teen reports of conversations were significant predictors of students' perceptions of STEM utility value after graduation. Overall, these results suggest that an intervention that targeted parents had direct effects on their teens' STEM course-taking in high school, and indirect effects on their teens' perceptions of STEM utility value. This suggests that parents, a largely untapped resource, can and should be viewed as powerful agents in the promotion of STEM motivation.

Apart from suggesting that future educational intervention research should consider targeting parents, Harackiewicz et al.'s (2012) study indicates that the onus of inspiring motivation does not lie solely on teachers or educational programs. There are numerous avenues for inspiring students, and parents have the ability to play an active role in that process. The fact that perceived utility value is a powerful motivator and a malleable construct suggests that there are numerous interventions that can work to motivate students. While we have addressed several utility value interventions in this article, there are certainly other effective ways to increase perceived utility value that future research should investigate.

Conclusion

The positive effects of utility value interventions reviewed here suggest that perceived utility value is an important construct and deserving of a prominent role in the motivational and educational literature. These findings suggest that educators and parents should try to enhance the perceived utility value of academic disciplines for students. While we know that an increase in perceived utility value has positive educational outcomes, research has yet to determine the *most* effective way of enhancing this value. The answer is likely complicated. As evidenced by the work of Durik and Harackiewicz (2007) and Hulleman and colleagues (Hulleman and Harackiewicz, 2009; Hulleman et al., 2010), different utility value interventions may be more effective for different types of people (Shechter et al., 2011; Durik et al., in press; Durik, et al., 2014). Moreover, the research by Harackiewicz et al. (2012) adds a different twist: in some cases, it may also be important to influence the perceived utility value of the person (e.g., parent) who communicates utility value to the target (e.g., teen, student). One avenue for future research is to investigate the context in which utility value information is presented (classrooms, family conversations, peer conversations) as well as the medium through which it is discovered (information from teachers, personal essays, informal interactions), which may provide insight into the development of even more effective interventions.

Academic Performance, Effects of Socio-Economic Status on

Brandon L Carlisle and Carolyn B Murray, University of California Riverside, Riverside, CA, USA

Abstract

The purpose of this article is to review the relationship between socioeconomic status and academic achievement. The complexity of this relationship will be examined by discussing factors such as socioeconomic segregation, school funding, teacher expectations, and academic climate. The effect that socioeconomic status can have on academic achievement is of global importance to educators, researchers, and policymakers, as they continue to address disparities in academic achievement and educational attainment. Efforts to ensure that all students receive an equitable educational experience are also discussed, with particular emphasis placed on the importance of effective schools.

Introduction

Accounting for differences in academic achievement among individuals and social groups has received considerable global attention from educators, researchers, and policymakers. Efforts to understand and account for these differences have involved an examination of individual student characteristics and the characteristics of their school environment (e.g., Coleman et al., 1966; Marjoribanks, 2003; Palardy, 2013). Socioeconomic status (SES) has been identified as one of the most commonly used contextual variables within research on academic achievement (Sirin, 2005). Research on SES and academic achievement has revealed a consistent relationship (Milne and Plourde, 2006); specifically, it is often the case that high SES is associated with greater academic achievement. Furthermore, the educational literature has provided evidence that SES is one of the strongest predictors of academic achievement and educational attainment (Reardon, 2011).

White (1982) outlined the most frequent applications of SES found in the educational literature. First, SES may be used as a covariate within quasiexperimental studies; in some cases, SES may not be of interest, although it relates to variables of primary interest, therefore researchers may choose to statistically control or adjust significant SES differences within a given sample. Second, SES can be used to improve the precision of experimental studies by controlling for it in analyses of covariance. Third, researchers can assess potential interaction effects, such as examining the possibility that a particular teaching method may be effective among high SES students but not among low SES students. Fourth, SES can be utilized to provide additional demographic information, which can facilitate efforts to determine external validity and accurately generalize empirical findings. Finally, SES can be used as a predictor variable when testing causal models of academic achievement and educational attainment.

While most researchers are in agreement regarding the importance of SES, White (1982) points out that SES has been defined and subsequently measured in a variety of ways across an abundance of empirical studies. Common indicators of socioeconomic status include income, occupation, and education (Sirin, 2005; White, 1982). Chapin (1928) defined SES as "the position an individual or family occupies with reference to the prevailing average of standards" (p. 99). Consistent with Chapin's definition, Mueller and Parcel (1981) much later described SES as an individual's or family's position in a societal hierarchy that dictates the degree to which the individual or family has access to wealth and power. Although the relationship between SES and academic achievement has been studied for many decades, the social sciences are continuing to address complex research questions pertaining to student level factors, school level factors, and the nature of the relationship within countries of developing or developed status. The purpose of this article is to review the relationship between SES and academic achievement and to discuss the implications of this relationship on educational attainment.

Country Income

The relationship between SES and academic achievement has been studied at a cross-national level as equitable education persists as an international concern. Researchers have progressively shown a strong interest in international comparative studies (Wiseman and Baker, 2005). For example, Heyneman and Loxley (1982, 1983) conducted a comparative study of high-income and low-income countries in order to further examine the nature of the relationship between SES and academic achievement. In high-income countries, they found evidence of a stronger association between individual student SES and academic achievement and a relatively weaker association between school-level factors (e.g., school and teacher quality) and academic achievement. However, their analyses also indicated that within low-income countries, school-level factors shared a relatively stronger association with academic achievement than did individual student SES.

In the literature, these contrasting results are often referred to as the *Heyneman–Loxley Effect* (HL Effect; Baker et al., 2002). The nature of the HL effect challenged the perception that weaker associations exist between school-level factors and achievement and stronger associations exist between individual student SES and achievement (Baker et al., 2002). Heyneman and Loxley (1983) concluded that the quality of schools and its teachers significantly influence the academic outcomes of students and within poorer countries, this effect seems to be more pronounced.

Several studies have been dedicated to replicating the HL effect but the results have not always been consistent. For

example, Riddell (1989) critiqued the HL effect by addressing an important methodological concern; specifically, analyses that revealed the effect relied on ordinary least squares regression, which did not take into account the hierarchical structure of the data (i.e., students nested within classrooms, classrooms nested within schools). Years later, Riddell (1997) reviewed 16 studies that implemented multilevel modeling in order to study academic achievement in developing countries and did not find evidence of the HL effect. Baker et al. (2002) also did not find evidence of the HL effect but posited that the effect may have diminished over time due to the increased efforts of poorer countries to invest in formal education as an economic strategy.

Heyneman (2005) argued that any failures to replicate the HL effect could be attributed to significant differences in samples of countries across studies. Heyneman also stressed that the influence of student SES is not consistent across societies and that it may differ due to grade level of students, gender composition of students, and how academic achievement is operationalized. While Baker et al. (2002) did not find evidence of the HL effect, a more recent cross-national study by Chiu (2010) found evidence that the association between individual student SES and achievement was stronger in richer countries, which is consistent with the HL effect.

Ethnicity

Ethnicity and SES are closely related; so much so that it can become difficult to disentangle the two constructs (Jussim et al., 1996). Regarding the student characteristics of the studies reviewed by White (1982) and Sirin (2005), it was found that minority status moderated the relationship between SES and academic achievement. Specifically, the mean effect size for Caucasian students was significantly larger than the mean effect size for minority students. This suggests that parental education, income, and occupation may be less related to achievement for minorities than issues such as the environment, the neighborhood and/or the school SES (Sirin, 2005).

When examining the relationship between SES and academic achievement, it is often the case that researchers need to consider the minority status or ethnicity of the student. The educational environment in which students find themselves can be extremely influential in their development. Unfortunately, there is disparate access to affluent educational environments; previous research has indicated that low-income, minority students are often subject to ineffective teachers, low teacher expectations, inadequate teaching aides, and defiant peers (Conchas, 2001). In the US, African Americans and Latinos are more likely to be members of low-SES families and attend low-SES schools (Williams and Collins, 2001); it is also the case that African Americans and Latinos tend to be underrepresented in higher education (Oakes et al., 2004). In Taiwan, Aborigines are a minority ethnic group that holds a disadvantaged socioeconomic position; they also tend to have lower academic achievements in comparison to Taiwanese students (Sung et al., 2013). Findings such as these illustrate the ecological validity of the relationship between SES, academic achievement, and ethnicity.

The ethnicity of students is an important contextual variable that can provide meaningful information about students; such information is relevant to research and application. Ideally, future research and *metaanalytical* studies will be able to code for multiple ethnic groups rather than only code for minority status. For example, it would be useful to determine if a specific ethnicity is associated with significantly different outcomes in comparison to other ethnic groups within a given country.

Immigrant Status

Similar to ethnicity, SES is an important factor when accounting for differences in academic achievement between native and immigrant students. Schnepf (2004) found a positive correlation between SES gaps between natives and immigrants and achievement gaps in reading scores. Relatedly, Buhlmahn (2003, as cited in Sung et al., 2013) found that students of immigrant status had lower academic achievements than native German students. Similarly, in a comparison of native students and low-SES, second-generation students, Alba et al. (2011) presented data that depicts achievement gaps in reading and mathematics within European countries and the US.

Understanding the influence of immigrant status and its relation to SES is a complex matter. The selection of an appropriate measure of SES requires careful consideration. For example, Schnepf (2004) argues that the SES indicator of parental education is problematic when comparing native and immigrant students because the quality of parental education may not be equal across countries. Furthermore, Schnepf also points out that it is important to consider an immigrant's country of origin, migration motives, and integration into the receiving country. Each of these factors may provide important contextual information when understanding the interrelationships between SES, academic achievement, and immigrant status.

Teachers

The quality and effectiveness of teachers can be very influential on student performance. The importance of teachers cannot be overlooked as they can directly influence student achievement. Teacher effectiveness and quality relate to SES because students of low-SES, low achievement, and minority status are less likely to be exposed to highly qualified, effective teachers (Lankford et al., 2002). This is due, in part, to the tendency for more qualified teachers to eventually seek employment in schools that have high-achieving students, greater resources, and strong administrative support (Hanushek et al., 2004; Rumberger and Palardy, 2005).

Research investigating the effects of teacher quality on academic performance has demonstrated that having access to highly qualified teachers can have a significant impact on student achievement. For example, in a cross-national study of teacher quality and mathematics achievement, Akiba et al. (2007) found that countries containing a higher percentage of students taught by highly qualified mathematics teachers (i.e., having earned a degree in mathematics, teacher certification, and at least 3 years experience) achieved a significantly higher national average mathematics score.

They also examined opportunity gaps in access to qualified teachers. Opportunity gaps were calculated by determining the percentage of high-SES students that have access to qualified teachers, determining the percentage of low-SES students that have access to qualified teachers, then calculating the difference between these two values. The largest opportunity gaps between high-SES and low-SES students were found in the countries of Syria, Chile, Taiwan, the US, and Hong Kong. Any opportunity gaps in access to qualified teachers can create a learning opportunity gap; this is an added disadvantage for low-SES students who may already experience a significant resource gap (Akiba et al., 2007).

An additional factor relevant to the issue of teachers is the influence of their expectations on student performance. Rosenthal and Jacobson (1968) demonstrated that teacher expectations could have a definite influence on the academic performance of students; specifically, if teachers have high expectations of their students, this can translate into stronger student performance. To further explore this outcome, Harris and Rosenthal (1985) conducted *metaanalyses* on the effects of teachers' expectations on the intellectual functioning of their students and discovered not only that these interpersonal expectancy effects occur but that their magnitudes are of substantial practical importance as well.

These *metaanalyses* supported the importance of behaviors that teachers may exhibit (e.g., praise, encouragement, long interactions, smiles) that mediate expectancy effects. In addition, these analyses provided support for a theoretical framework involving the mediation of interpersonal expectancy effects. Specifically, teachers who hold positive expectations for a student will tend to display a warmer affect, express more positive feedback, provide more input with regards to the quantity and difficulty of material that is taught, and increase the amount of student participation by offering more response opportunities (Harris and Rosenthal, 1985).

This research is pertinent to the discussion of SES because previous research has indicated that teachers hold higher expectations and more positive attitudes for high-SES students, in comparison to their low-SES counterparts (e.g., Auwarter and Aruguete, 2008). Furthermore, in relation to SES, Jussim et al. (1996) found that students of low-SES backgrounds were more susceptible to expectancy effects. They posited that low-SES students may have "reduced social and psychological resources for combating erroneous teacher expectations" (p. 371).

Academic Climate

The academic climate a student experiences can also have an impact on the relationship between SES and academic achievement. Evaluating academic climate may consist of determining the types of messages students receive from their peers, teachers, and administrators with regard to academic achievement and educational attainment. It can also involve an assessment of school safety, the average number of hours spent completing homework per week, and the average number of college prep courses taken (Rumberger and Palardy, 2005). Additionally, a more comprehensive approach to understanding academic climate has considered factors both in and out of school (e.g., home atmosphere, neighborhood unemployment rate).

Lee et al. (1999) studied how academic achievement is related to student social support and school academic press. They defined student social support as the personal relationships between a student and individuals (e.g., peers, parents, and teachers) who are able to provide them with encouragement and assistance in and out of school. Academic press was defined as the extent to which school members (e.g., students, teachers, and administrators) emphasize academic success and satisfying standards of achievement. Their analyses revealed that social support and academic press were positively correlated with academic achievement in the subject areas of mathematics and reading. Furthermore, the constructs of academic press and social support were related to SES; specifically, they found that students who attended low-SES schools were least likely to experience the ideal combination of high social support and high academic press.

Socioeconomic Segregation

Throughout the world, there are students belonging to affluent families that receive a distinguished education and students belonging to low-income families that receive a substandard education. These disparate educational experiences contribute to the academic achievement gap that has been a source of concern for decades. The existence of socioeconomic segregation should be of concern because of its relationship to individual student performance (e.g., Bankston and Caldas, 1996; Rumberger and Palardy, 2005). In their analysis of cohort data, Duncan et al. (2013) found that the familial income gap between low-SES children and high-SES children accounted for significant amounts of the academic achievement gap. According to Duncan and Murnane's (2011) conceptual model, high-SES children are more likely to have greater access to high quality child care, schools, and settings that enhance the development of important skills related to education while low-SES children may have parents who cannot afford such resources.

In reaction to the unequal educational experiences associated with socioeconomic segregation, socioeconomic integration (e.g., low-status immigrants attending more affluent schools, low-SES students attending high-SES schools) has been discussed as a potential means to reduce the achievement gap and improve equity in education (e.g., Alba et al., 2011; Ryan and Heise, 2002). Rumberger and Palardy (2005) conducted a study to further investigate the effect of socioeconomic segregation on academic performance. Their analyses were conducted on hierarchical data that included students nested within schools as they were followed from Grades 8 through 12. They found that the average SES of a student's school had a near equal influence on achievement as individual student SES. Additionally, school SES had a similar influence on low-SES students and high-SES students.

Further analysis revealed that the effect of school SES on academic outcomes was no longer significant after controlling for school policies and practices (e.g., teacher expectations, academic climate). Based on these results, Rumberger and Palardy concluded that socioeconomic integration may not be

necessary, provided school policies and practices can be reformed. It may be the case that improving low-SES schools in this fashion would be more effective and realistic, in comparison to mandated socioeconomic integration.

Disparate Funding

The inequity created by socioeconomic segregation is related to the amount of funding a school district receives as well as the amount of funding a school receives from their respective district. Governing bodies are faced with the responsibility of ensuring that schools receive sufficient funding so they can provide equitable, effective education to all of its students (Augenblick et al., 1997). This objective can become more challenging for low-income countries; the amount of funding schools receive can depend on the wealth of a nation and how they disperse public expenditures on schooling (Colclough and Al-Samarrai, 2000).

In their review of school funding equity, Augenblick et al. (1997) demonstrate that SES is associated with school funding by providing evidence that school districts with wealthier residents tend to receive significantly higher per-pupil funding. It is also the case that disparities in funding can exist within a school district. Condron and Roscigno (2003) conducted a study that included urban elementary schools of diverse racial and SES composition. They found that within districts, instructional per-pupil expenditure and percentage of students eligible for free or price-reduced lunch were negatively correlated. Further, they found that operations and maintenance per-pupil expenditure were also negatively correlated with the percentage of students eligible for the free or price-reduced lunch program. This provides evidence that it may be insufficient to only address disparate school funding between districts; disparate school funding within districts is also worthy of close attention and resolution.

Augenblick et al. (1997) provided recommendations as to how districts should proceed in funding its schools. These recommendations include: districts establishing a base level of per-pupil funding that is consistent with expectations of academic achievement; governing bodies distributing funding to districts and then districts distributing funding to schools, which should be based on relative needs such as students enrolled in high-cost programs, prevalence of students at risk of failure, and the size of the school; and governing bodies providing equal support for the construction and maintenance of school facilities.

For example, within the United States, a potential solution could involve states being encouraged to ensure more equitable funding through incentives provided by the federal government; the establishment of a more significant federal role in financing education is a matter of collective and political will (U.S. Department of Education, 2013). Among other recommendations, the U.S. Department of Education's Equity and Excellence Commission calls for new federal funding that should be allocated to schools with high concentrations of low-SES students and the expansion of the government's authority to ensure the equity of school financing. Additional funding to schools with high concentrations of low-SES students could facilitate efforts to accrue new educational resources and, if necessary, reform the policies and practices of these schools.

Intervention

Closing the achievement gaps has become an important issue for many countries (Sung et al., 2013). Reform efforts have been discussed and implemented throughout the world; these efforts aim to improve the education practices believed to influence learning for low-performing students, and thus decrease the achievement gap (Feuer et al., 2002; Hargreaves, 2000; Pressley et al., 2004). One such program, developed by the United States is the 'no child left behind' (NCLB) Act, which was implemented in order to aid disadvantaged children. This program expanded the federal role in public education by rewarding schools that set high standards and established measurable goals to improve individual outcomes in education. While the U.S. Department of Education reported that student achievement had improved in reading and math, critics of the program argued that these statistics were misleading. One criticism was that creators of the standardized tests were accused of making the assessments less challenging so that it was easier for schools to significantly improve.

While there is debate surrounding the effectiveness of intervention programs, some interventions seem to have narrowed the achievement gap between high and low socioeconomic groups. For instance, the Finnish government has significantly invested in its country's education and the implementation of educational policies that include comprehensive schooling with no tuition or book fees for its students (Lavonen and Laaksonen, 2009). According to the findings of the Program for International Student Assessment (PISA), the achievement gap in Finland has significantly reduced over time.

Still other interventions have not had a significant impact on academic outcomes and disparities in performance. For example, the French government implemented the Zone of Education Priority program; this intervention established new teaching projects and distributed more resources to schools in low-SES areas (Sung et al., 2013). In their evaluation of the effectiveness of this program, Bénabou et al. (2009) found evidence to suggest that the program did not have a significant impact on student success, which was measured by several measures (e.g., obtaining a diploma, performance on national examinations). In the United Kingdom, the Ethnic Minority Achievement Grant was developed to reduce the achievement gap between immigrant, minority students, and native English students. An evaluation of its effectiveness revealed that the intervention contributed to a partial reduction in the achievement gap but significant differences between ethnic minority achievement and national average achievement remained (Tikly et al., 2005). In South Korea, the government implemented an education welfare action zone policy that was designed to provide educational resources to low-income areas; this intervention was able to increase positive educational activities among participating schools (i.e., increased student usage of school libraries) however their results did not reveal significant changes in academic outcomes among low-SES students (Lee, 2008).

For many intervention programs, the jury is still out. While SES may complicate the ability to establish a standard of education that prepares all students for success, the characteristics of a successful school can be achieved if teachers and administrators are willing to exert the necessary effort. See Edmonds (1979) and other researchers (e.g., Purkey and Smith, 1983) for a discussion. Although these researchers acknowledge that family SES does indeed make a difference, they were able to identify schools where the student populations were comprised of low SES students who were achieving well academically. Edmonds identified the following seven characteristics that these schools had in common: (1) strong administrative leadership, (2) clear school mission, (3) high expectations for student success, (4) frequent monitoring of school performance, (5) focus on basic skills, (6) safe and orderly environment, and (7) a focus on home–school relations. These characteristics can serve as clear tenets for an educational system that needs to remedy disparities in academic experiences and outcomes. Furthermore, if schools and faculty members are committed, it is possible that these characteristics can be met without significant changes to school funding. In the words of one highly successful educator:

> Effective schools do not attempt to eliminate the achievement gap that separates low-SES children from high-SES children: they raise the floor below which nobody falls.
>
> Ronald Edmonds (1986: p. 101)

To date, globally the achievement gap between high- and low-SES students still persists. This should not come as a surprise since none of the countries attempting to reduce the SES achievement gap have implemented all seven characteristics of 'effective schools.'

Academic Research and Employment: Recent Changes in Europe and the United States

Elke Park and Hans Pechar, Institute of Science Communication and Higher Education Research, Alpen Adria Universität, Vienna, Austria

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Academic research is increasingly carried out on the basis of externally sponsored research projects. This article focuses on the transformative role of new funding mechanisms and its influence on academic work and careers. First, we will outline the increase in externally funded research at higher education institutions in Europe and the United States over the last decades. Second, we will discuss the impact of changes in the funding regime on academic careers and employment conditions, most notably on the postdoctoral phase. We will present criticism of recent developments and conclude with an outline of the corresponding, emerging governance regime in higher education, network governance.

In the following we address profound, ongoing changes in the structure of academic work and research over the last three decades. These changes correspond to more general transformations in the nature of work also affecting other social subsystems: a turn toward project-based, nonpermanent work contracts and more flexible, network-like institutional environments (see Boltanski and Chiapello, 2005). At universities, fixed-term and part-time labor – often externally funded – is replacing tenured full time positions (Schuster and Finkelstein, 2006). Academic research is increasingly carried out in the framework of temporarily delineated projects. In an ever shifting network-like structure, groups or research teams continuously form anew to apply and compete for project funding. The *New Spirit of Capitalism* (Boltanski and Chiapello, 2005) certainly deeply permeated academe since the onset of New Public Management (NPM) policies in the 1980s and 1990s.

The rise of neoliberalist policies in most Western countries since the 1980s has set strict limits on public spending for education and research. Burton Clark argued that "governments increasingly indicate that they are not prepared to pay the unit costs of mass higher education at the level of elite education" (1997: 247). However, central to the idea of New Public Management, or rather the notion of the managerial or entrepreneurial university, is not only the quantitative restriction of public funding – i.e., increased budgetary restraints – but, more importantly, the introduction of qualitative changes in the way these funds are distributed. Under the premises of accountability, research funds are no longer distributed unconditionally, or untargeted, in the form of general university funds. Rather, higher education institutions act as 'applicants' having to qualify and continuously requalify for funding in a competitive process. The distribution of funds for university research via competitively awarded projects and grants can certainly be regarded as one of the central axioms of NPM-inspired approaches to the governance of higher education (for an overview of NPM policies in higher education, see Ferlie et al., 2008).

The vital importance of education for a 'knowledge-based society' and the growing economic relevance of research which resulted in an unprecedented expansion of higher education and research systems did not necessarily lead to better and more favorable conditions for the respective social subsystems. On the contrary, most constituencies regard the changes of the last decades as a burden. This is not only true for students who complain about increasing private contributions to education – as it is the case in the US – or the decrease in quality of mass higher education in European countries retaining open access policies. Academics bemoan deteriorating working conditions and in particular junior academics complain about the difficulty to embark on a stable career. The increased significance of knowledge resulted in qualitative changes in the relationship between higher education and research and public funding bodies.

The Increase and Impact of External Research Funding on Academic Work

> As universities have transformed into modern research complexes, the organizational character and rhythm of academic work changed to accommodate the **increased centrality of externally sponsored research**.
>
> Gumport, 2011: 367

Recent data from the US and Europe illustrate the steep rise in externally sponsored academic research or project-based funding at universities over the last 15 years. For example, in the US the National Science Foundation's support for university research and development more than doubled from 1997 to 2012.[1] In Germany so-called third-party funds almost tripled during that period, and in Austria – a country which experienced a relatively drastic turn toward NPM-inspired university governance in the mid-2000s – a more than fourfold increase in external, project-based university funding took place.[2] At the same time, general university funds remained comparatively stable. In some instances – for example, the University of California system – general state funds even declined during the same period.[3]

These changes in the funding landscape have had tremendous effects on academic work and academic careers. General university funds which provide the basis for permanent, tenured positions are stagnating or even declining while on the other hand available work on research projects is

increasing. This has led to shifts in the personnel structure at universities.

University research is increasingly following a project logic with a defined beginning and end, and it is carried out in teams. In the social and behavioral sciences as well as in other fields of science it is no longer – if it ever was – a single professor elaborating theories on society in the privacy of his or her office. Instead, the data collection and subsequent analysis of data sets in large empirical research projects require a team effort. In commissioned or sponsored research, project teams generally consist of a Principal Investigator (PI) as the project leader providing the general lines of inquiry – usually a professor or other tenured member of a university – and several postdoctoral scholars and graduate research assistants/PhD students employed on the basis of 'soft money' or external funds. The latter typically do the groundwork and carry out the research, sometimes they are also tasked with writing the proposals. These projects – and thus a large part of university research – require flexible, readily available researchers willing to take on fixed-term work. Clark Kerr has called these academic workers 'the un-faculty' (2001: 49).

The numbers of postdoctoral appointees in science in the US increased rapidly from 1998 to 2011, in the social sciences postdoctoral appointments almost doubled in that period. [4] On the other hand, 'ladder faculty' (tenured or tenure-track positions) has grown at a much smaller rate (see Schuster and Finkelstein, 2006 for the US). On the European continent, the trend is equally, if not slightly more pronounced. At German higher education institutions, externally funded academic staff doubled in only 7 years (2005–12) whereas staff employed on the basis of general university funds only increased by 33%.[5] Also, at Austrian universities, the numbers of 'core staff' have stagnated while the fastest growing group of 'academic workers' were pre- and postdoctoral positions on the basis of external funds or 'project money.'[6]

As a result of the growing relevance of research projects and the increase in numbers of postdocs, the nature of the postdoctoral phase in academic careers is changing.

The Postdoctoral Experience: 'Project Workers' in the US and Europe

The postdoctoral phase is considered the most difficult and high risk, critical phase of an academic career (Brechelmacher et al., 2015). It falls between the completion of the doctorate and entering into permanent, tenured employment. In the US, postdoctoral positions are typically funded on the basis of grant money. They are positions offered in the framework of research projects or external research grants and contracts.[7]

The NSF and the National Institutes of Health (NIH) only recently defined a postdoctoral scholar as an individual who has received a doctoral degree (or equivalent) and is engaged in "a temporary and defined period of mentored advanced training to enhance the professional skills and research independence needed to pursue his or her chosen career path."[8] Postdocs are considered trainees, however, under specific circumstances they can also act as principal investigators. Having the NSF/NIH officially recognize the postdoc position by establishing a definition was an important milestone in the recognition of the contributions of postdocs. Until recently, as Cathee Johnson Philips of the National Postdoctoral Association claims, "postdocs were invisible […]. Most institutions did not know how many postdocs they had, due to the nature of the position."[9]

However, the composition of the academic workforce is changing, as the above numbers illustrate for both the US and Europe. "The […] scientific enterprise has become increasingly dependent upon postdocs to conduct research and maintain its position in the global research enterprise."[10] Today, postdocs account for much of the labor in academic research. Henry R. Bourne (2013) points out for the biomedical sciences that "the laboratory workforce [is] largely made up of PhD students and postdoctoral researchers, mostly supported by research project grants, with a relatively small number of principal investigators leading ever larger research groups." And he concludes provocatively that, today, "trainees equal research workforce."

Universities rely on post- (and pre-)doctoral appointees to carry out their – externally funded – research. The conditional and temporary nature of project funded research takes its toll on those embarking on academic careers. Research projects generally cannot generate permanent jobs as universities are reluctant to create permanent positions on the basis of external funds (see Brechelmacher et al., 2015). If funds run out, even experienced researchers will be asked to leave.

Due to an oversupply of postdocs and a high level of competition, it is becoming harder to secure a position on the tenure track. As a result, young academics are often forced to take on one postdoc position after the other. "In too many instances 'postdoctoral training'—when a young scientist is learning new approaches and techniques towards independence—has turned into 'postdoctoral employment', with the postdoc remaining at the same professional rank with little advancement or additional training" (National Research Council, 2005). However, as *Johnson Phillips* argues, "if a person remains in a postdoc [position] for longer than five years, their chances of having a successful career in science diminishes."[11] Some academic job seekers are already "wondering if there is a stigma attached to holding too many postdoc/soft money positions when looking for a tenure-track position."[12]

While on the one hand, successful postdoctoral work has increasingly turned into a prerequisite for obtaining a tenure-track position or permanent employment, on the other hand, "postdocs are starting to become a substitute for real jobs."[13] One could raise the question if the notion of what constitutes a 'real job' is not in the process of changing.

Further Effects of Project-Based, External Funding in Academe

Beyond the issue of uncertain working conditions and the high-risk nature of project-funded employment, project-based funding schemes affect the way academic research is carried out in other ways as well: the debate centers mostly around the fact that the successful acquisition of 'external' funding has become an indicator for quality on the institutional level as well as

a means to measure the scientific reputation of individuals in academe (see Münch, 2006: 440).

Richard Münch, a critic of the increasing centrality of conditional funding in the German higher education system, maintains that an increasing reliance on external funds favors 'normal science' – standardized mainstream research. Due to limited project duration, the probability of delivering results in a certain timeframe becomes a central factor in funding decisions and thus puts riskier research endeavors at a disadvantage (Münch, 2006: 448). The peer-review process – while mostly able to filter out research proposals of lower quality – can also block new, creative approaches outside of existing 'schools of thought.' In the funding process, both sides strive to reduce uncertainty, as Münch argues, and thus large, mostly quantitative research projects are favored, as well as those building on and extending formerly approved projects: "Serial project funding along the same lines over and over again" hinders innovation and the creation of new knowledge especially in the social sciences (Münch, 2006: 449). To break this cycle, Münch advocates the explicit use of external funding to reward more risky scientific endeavors and research off the beaten track, as 'normal science' is carried out at higher education institutions anyway.

The ability to raise external funds has become a measure of scientific excellence and an indicator of academic potential. As a result, the amount of soft money raised by an academic is increasingly determining his or her 'value' in the academic job market. The acquisition of external funds thus plays a decisive role in the hiring and recruitment processes of academic personnel.

Another consequence of the increased reliance on external funding in university research is a certain realignment of tasks, affecting what it is that professors actually do: less and less do PIs find time to engage in actual research themselves. Their time is less spent on scientific inquiry and increasingly devoted to acquiring funding. Further, their contributions to the projects are becoming more and more managerial. A recent article entitled "Dr. No Money: The Broken Science Funding System - Scientists spend too much time raising cash instead of doing experiments" quotes a 2007 US study according to which university faculty members spend about 40% of their research time navigating the bureaucratic labyrinth, and the situation is not different in Europe.[14]

With tenured faculty or PIs outlining the general direction of research and PhDs and postdocs carrying out the actual research, sponsored projects have taken on a training function in higher education. As Brechelmacher et al., 2015 show for Europe, a predoctoral position on the basis of soft money is often regarded as a 'typical' entry position into an academic career.[15] Research training increasingly takes place in the framework of externally funded projects, and these projects fulfill a vital role in the training of the academic workforce.

Finally, current funding schemes tend to create a dynamic similar to what Merton referred to as the 'Matthew principle' in science whereby formerly successful recipients of research funds will be more likely to receive future monies than others (see Merton, 1968). A concentration process thus occurs (see also Kerr, 2001: 47). Differentiation in the US higher education system has traditionally been high. Around half of total NSF funding in the social sciences went to only 20 of around 200 supported institutions in 2013.[16] At German universities, a concentration process is currently in full swing, and efforts like the so-called Excellence Initiative propel these dynamics even further. Ten out of a total of 100 institutions in the social and behavioral sciences received half of all DFG funding in 2008–10.[17]

Network Governance – Conceptualizing Project Work

The 'project logic' or project orientation of research has deeply permeated and transformed higher education and the way university research is carried out. Boltanski and Chiapello's concept of a 'justificatory regime' of projects – a project-based society or: 'cité' – provides an insightful framework that also applies to higher education and university research (see also Holtgrewe, 2010). Following Boltanski and Chiapelli "the project-oriented systemic logic values adaptability, flexibility, polyvalency, mobility, initiative, autonomy, risk-taking, and openness to new people, possibilities, and information" (Markin, 2008). These are qualities expected of individuals attempting to embark on an academic career today.

Most important, however, is the fact that projects are essentially based on networks: "The project is the occasion and reason for the connection" (Boltanski and Chiapello, 2005: 104). Thus, the concept of 'network governance' emerged as a corresponding governance paradigm. The concept was adapted to higher education, among others, by Ferlie et al. (2008), Paradeise et al. (2009) or Bleiklie et al. (2011). It is defined as a "form of multi-level governance, encompassing a greater range of actors engaged in shared decision-making processes and interactions between various layers of influence" (Campbell, 2013: 206) and refers mostly to "new kinds of policy networks related to external research funding mechanisms, evaluation and accreditation agencies" (Bleiklie et al., 2011: 176). Network governance – power and decision-making processes rooted in shifting networks – can also be viewed as a by-product and consequence of NPM-inspired governance schemes (budgetary restraints, conditional funding, increased level of competition, heavier emphasis on performance (Ferlie et al., 2008).

Network governance in higher education is best exemplified by the process of peer review: crucial decisions in academe – which projects get funded, who gets hired – are no longer taken by the institutions or institutional players (such as the department, the university, or the ministry of education) themselves, but are transferred or outsourced to superimposed networks of experts. Recruitment decisions are no longer or increasingly less taken by the actual organization itself, rather they are determined by external experts in so-called peer-review processes.

Summary and Outlook

The phase of massification of higher education in the second half of the twentieth century saw a steep increase in public research expenditure and with it the rise of the 'research project.' However, growing monetary support for academic research was accompanied by a decrease of trust in higher education

institutions. A decreasing part of research funding is distributed unconditionally to universities via lump-sum agreements. Rather, funding is designated for specific purposes and only the 'best' applicants are rewarded in a competitive process. A network of 'peers' is to determine the quality of the proposals. As there is no guarantee that these monies will flow permanently to institutions, they outsource the risk. Thus, research is increasingly carried out by people who are employed on the basis of external funds, researchers who are 'external' to the institutions they are actually working at, rather than by tenured staff holding permanent positions at the institution. With shrinking general university funds and an increasing amount of academics employed on the basis of 'soft money,' it becomes difficult to reach tenure for the larger part of the research workforce at universities. The question remains if project-shaped work environments – continuous reapplication and revalidation for work/funding – is a specific characteristic of academic work or, rather, a general social trend.

End Notes

1. The same holds true for total federal US support for university science & engineering R&D. Tables on "Federal Support for University R&D by Agency" as well as "University S&E R&D Funding by Source, 1990–2012"; based on data from the NSF's HERD survey available online at http://www.aaas.org/page/rd-colleges-and-universities. Data in constant 2014 dollars.
2. For Germany: An increase of 170%, adjusted by inflation an increase of 130%. Abstract

Positive academic self-concept has been considered one of the most important indicators of educational success. Empirical evidence across divergent educational and cultural contexts supports (1) a hierarchical multidimensional model of self-concept, (2) reciprocal causal relations between academic achievement and corresponding self-concepts, (3) the use of both internal and external frames in making self-concept judgment, and (4) the importance of both social comparison and reflected glory effects.

Self-concept is defined as "a person's self-perceptions that are formed through experience with and interpretations of one's environment" (Marsh et al., 2011; see also Shavelson et al., 1976). It is affected in particular by evaluative information from other people (e.g., teachers, parents, classmates), such as outcome feedback, reinforcements, and attributions for one's performance. When a person interprets one's environment subjectively, this process may involve the use of objective measures (e.g., standardized achievement tests) as well as dispositional (e.g., personality; Marsh, 2008) and situational (e.g., average achievement levels of a school) factors.

Thus, self-concept is one of the most important constructs in many fields of psychology. This article concentrates on the notion of academic self-concept, the improvement of which is a major educational goal or outcome given that high self-concept is a positive indicator of educational success. Academic self-concept is also an important educational mediator in that high self-concept leads to other desirable personal or educational outcomes. Its importance was summarized neatly by Branden (1994),

> *I cannot think of a single psychological problem* – from anxiety to depression, to under-achievement at school or at work, to fear of intimacy, happiness or success, to alcohol or drug abuse … – *that is not traceable, at least in part, to the problem of deficient self-esteem*. (p. xv)

Although self-concept is one of the oldest and most important constructs in the social sciences, its theoretical development has been slow, particularly in the days of behaviorism. However, since the 1980s, research on self-concept has progressed on the basis of advancements in psychological measurement instruments, research methodologies, and theoretical refinements (e.g., the multidimensional model; see Marsh, 2007; Marsh et al., 2011).

Hierarchical Multidimensional Structure

The development of the theoretical model of self-concept has differentiated between within-network and between-network research. In the former type of research, scholarly interest focuses on the internal structure, features, and attributes of self-concept, whereas in the latter researchers concentrate on how self-concept is related to other constructs beyond its own conceptual domain.

Global Self-Esteem vs Multidimensional Self-Concept

Typically, within-network research is seen to be more important than between-network research during the early stages of theory building. As Marsh and Scalas (2010: p. 11) noted, "The determination of whether theoretically consistent and distinguishable dimensions of self-concept existed, and their content and structure [within-network research], should be prerequisite to the study of how these dimensions, or overall self-concept, are related to other variables [between-network research]."

Current models of self-concept can be traced back to the multidimensional hierarchical model proposed by Shavelson et al. (1976) (see **Figure 1**). In this hypothetical model, situation-specific (e.g., verbal, numeric) self-concepts are at the base of the hierarchy, self-concepts of broader domains (e.g., social, academic) are in the middle, and the most generalized and global self-concept (known in general as self-esteem) is at the top.

Despite this heuristic multidimensional model, unidimensional instruments that measured a single self-esteem factor (e.g., Coopersmith, 1967) predominated before the mid-1980s, probably because of the lack of strong empirical support for the multidimensional model at that time. Indeed, this issue of whether self-concept is unidimensional or multidimensional has remained the focus of ongoing debate (Marsh and Craven, 1997; Rosenberg et al., 1995; Suls, 1993). With the development of instruments that were much stronger psychometrically, empirical evidence began to show the necessity and usefulness of differentiating between the dimensions that comprise self-concept. A number of new multidimensional instruments that were developed typically contained specific self-concept scales for the academic (e.g., verbal, numeric), social (e.g., with friends), physical (e.g., physical competence, attractiveness), emotional, and global (i.e., self-esteem) domains (see Marsh and Scalas, 2010). Reviews (e.g., Byrne, 1984, 1996; Hattie, 1992; Wylie, 1989) recommended the use of the Self Description Questionnaires (SDQ), which

Figure 1 The multidimensional, hierarchical model of the self-concept construct. The box that consists of dashed lines around the nonacademic self-concept factors is used to distinguish these from the academic self-concept factors, but does not imply that there is a single higher order non-academic factor, as is hypothesized for the academic factors. The unlabeled boxes at the bottom of the hierarchy are used to show that the model posits additional levels in the hierarchy and even more domain-specific components of self-concept than those that are presented explicitly (e.g., mathematics self-concept might be divided into different mathematical topics, such as algebra, trigonometry, and calculus, and each of these could be further subdivided into specific components that are relevant to each of the mathematical subjects). Reprinted with permission from Shavelson, R.J., Hubner, J.J., Stanton, G.C., 1976. Validation of construct interpretations. Review of Educational Research 46, 407–441.

targeted specific age groups (e.g., SDQ I, II, and III were designed for use with children, adolescents, and young adults, respectively; Marsh, 2007).

Research has since shown that certain measures of self-concept can even be used with very young children. For example, Marsh et al. (1991, 1998) developed an individually administered procedure for SDQ I for use in younger children (aged 5–8 years), which has acceptable psychometric properties even for younger special education students (Grades 2–6) who have mild intellectual disabilities (intelligence quotient 56–75) (Tracey et al., 2003). Although scores for the different dimensions become more differentiated with increasing age, and their relations with external indicators also strengthen (e.g., increasing correlations with achievement), research suggests that young children can differentiate between multiple dimensions of self-concept at a much earlier age than was believed previously.

Empirical Evidence: Low Correlations among Self-Concept Domains

These multidimensional characteristics of self-concept have been supported in several areas of empirical research. First, the advanced confirmatory factor analyses that have been developed over recent years have shown that academic self-concepts are virtually uncorrelated or even negatively correlated with nonacademic self-concepts and self-esteem. Multitrait multimethod analytical techniques on the ratings from different instruments and by different significant others (teachers, parents vs students) also support the discriminant (i.e., differences across multiple dimensions of self-concept) and convergent (i.e., similarity across instruments and raters) validity of multidimensional self-concept ratings. Further, self-concepts have been found to be much more differentiated than academic achievement (or school grades) in the corresponding domain (Marsh and Craven, 2006).

Second, different domains of academic achievement (e.g., verbal achievement and mathematical achievement) tend to be correlated substantially, as does each domain of achievement with its matching self-concept, for example, verbal achievement with the verbal self-concept. However, different domains of self-concepts (e.g., verbal self-concept and mathematics self-concept) are uncorrelated in general. In other words, academic subjects share a large percentage of common variance (i.e., general achievement or intelligence; they are substantially correlated and hierarchically ordered), whereas their corresponding self-concepts do not.

Third, in structural equation models that relate self-concepts to other constructs, although different domains of academic achievement or school grades have predictable relations with the matching and nonmatching domains of self-concepts, they are unrelated in general to self-esteem.

In light of the foregoing empirical evidence, the multidimensional hierarchical model of Shavelson et al. (1976) was revised in the 1980s. Specifically, although all first-order academic-subject-specific academic self-concepts are grouped under the second-order academic self-concepts in the original hierarchical model, subsequent empirical results showed much weaker (indeed, close to zero) correlations between different first-order domains of self-concepts (e.g., mathematics and verbal self-concepts). The original model of Shavelson et al. was thus revised into the Marsh/Shavelson model, in which the second-order academic factor was divided into domain-specific factors (e.g., verbal and mathematical self-concepts) (Marsh et al., 1988).

Not only did the revised model fit the data much better than the original, but stronger relations were also found when domain-specific self-concepts were used. For example, Marsh and Yeung (1997) showed much stronger effects of these domain-specific self-concepts (vs general self-esteem) on subsequent coursework selection, which demonstrated the importance of domain-specific academic self-concept as compared with that of general self-esteem. These empirical results also suggested that the hierarchical structure was weaker than anticipated originally, whereas multidimensional characteristics appeared to be more salient, useful, and important.

Educational Implications

Empirical findings demonstrate that students are able to evaluate their competencies in a number of academic subjects. Consequently, researchers are encouraged to use scales that measure self-concept in specific academic subjects (e.g., using the mathematics self-concept) – such as by applying the Academic Self Description Questionnaire (Marsh, 1990b) or the SDQ (Marsh, 2007) – in addition to or instead of adopting general academic self-concept scales.

According to the multidimensional perspective, any type of self-concept intervention, if successful, should have positive effects only on specific targeted or closely related facets of self-concept rather than unrelated ones. Indeed, this approach to construct validation has been supported in enhancing physical fitness (Marsh and Peart, 1988), and in Outward Bound program (Marsh et al., 1986) and a wide range of other studies (Haney and Durlak, 1998; Marsh and Craven, 1997; O'Mara et al., 2006). Using the global self-concept approach, Haney and Durlak's (1998) meta-analysis showed the moderate positive effect ($d = 0.51$ over 460 effect sizes) of a self-concept enhancement program. This was much smaller than the effect observed in the subsequent update and reanalysis by O'Mara et al. (2006) ($d = 1.16$), who used the multidimensional approach.

The implication of these findings is that, in educational interventions, teachers must take into consideration the multidimensional characteristic of self-concept in their instructional designs in order to enhance this construct. Further, positive educational feedback must be focused specifically on the targeted academic subject or set of skills. Vague or broadly applied enhancement programs that aim to raise the general level of self-concept in order to improve performance in a specific academic subject might be ineffective.

Causal Ordering of Academic Self-Concept and Achievement

Although the majority of interest in academic self-concept might stem from the belief that students can improve their academic achievement by boosting their level of self-concept in different areas (Byrne, 1984; Marsh, 1990b), there has been a distinct lack of empirical support before the 1990s. In other words, although the specific domains of academic achievements have been shown to be correlated with their respective self-concepts as discussed earlier, there are practical (e.g., in terms of actual educational interventions) and theoretical reasons to differentiate the cause from the outcome.

Self-Enhancement and Skill Development Models

Two hypothetical models have been proposed to explain the relation between academic achievement and academic self-concept, namely, the self-enhancement and skill development models (see Marsh and Martin, 2011). In the former, self-concept is thought to be the predominant cause of subsequent achievement, whereas the reverse is true in the latter. Specifically, researchers would like to understand empirically whether a more positive academic self-concept is the cause of better academic achievement or whether better academic achievement leads to a more positive academic self-concept.

Although an experimental study using control groups might be an appealing approach to solve such a problem of causal ordering, the empirical manipulation of achievement and self-concept might not be easy or practical. For example, it is difficult, if possible at all, to assign students to a high-achievement group and then raise their levels of academic achievement experimentally without inducing other changes. These difficulties in experimental design have led to the use of longitudinal panel data instead, with domain-specific self-concept and achievement data collected several times (at least twice; thrice in **Figure 2**). Logically, prior achievement should positively affect subsequent achievement (e.g., see **Figure 2**, Time 1 achievement (T1-ACH) on Time 2 achievement (T2-ACH)), because students who have higher achievement in the first round of data collection (T1) would tend to have higher achievement in the second round (T2). Similarly, prior self-concept should also influence subsequent self-concept positively, because students who evaluate themselves highly at T1 would also tend to evaluate themselves more positively at T2.

The most important theoretical questions are (1) whether better prior achievement also benefits subsequent self-concept (e.g., T1-ACH → T2 academic self-concept (ASC; **Figure 2**) and (2) whether a more positive prior self-concept also benefits subsequent achievement (e.g., T1-ASC → T2-ACH; **Figure 2**). Specifically, as presented in **Figure 2**, after statistically controlling for the two main effects (T1-ACH on T2-ACH; T1-ASC on T2-ASC, etc.), we are interested in whether cross-lagged paths exist. With the development of stronger assessment instruments, research designs, and analytical methodologies, empirical research and meta-analyses (Marsh and Craven, 2006; Valentine et al., 2004) have supported the reciprocal effects model (REM; Marsh, 1990a), which proposes that both types of effects (path) are statistically significant and important. Although it is accepted widely that

Figure 2 Prototype causal ordering model to test self-enhancement, skill development, and REMs. In this full-forward, multiwave, multivariable model, multiple indicators of ASC and ACH are collected in three successive waves (T1, T2, and T3). Each latent construct (represented by ovals) has paths that lead to all latent constructs in subsequent waves. Within each wave, ASC and ACH are assumed to be correlated. In the first wave, this correlation is a covariance between two latent constructs, and in subsequent waves, it is a covariance between residual factors. Curved lines at the top and bottom of the figure reflect correlated uniqueness between responses to the same measured variable (represented by boxes) collected on different occasions. Paths that connect the same variable on multiple occasions reflect stability (the solid black paths), but these coefficients typically differ from the corresponding test–retest correlations (which do not include the effects of other variables). Light gray arrows reflect effects of prior achievement on subsequent academic self-concept, whereas dark gray arrows reflect the effects of prior academic self-concept on subsequent achievement. British Psychological Society, Leicester, UK. http://www.bps.org.uk/publications/bps-journals/journals-copyright-authors/journals-copyright-informationInformation.

achievement is a determinant of subsequent self-concept, the authors' main research interest lies in demonstrating the existence of the self-enhancement path (ASC → ACH).

Previous research has also shown that the above-mentioned REM, which relates achievement and self-belief, can be applied to a range of academic subjects (i.e., not just the most widely studied subject of mathematics), as well as nonacademic areas (e.g., physical self-concept with gymnastics and elite swimming) and psychological domains (e.g., self-efficacy) (Guay et al., 2003; Marsh and Craven, 2005; Valentine and DuBois, 2005; see meta-analyses, Valentine et al., 2004). Further, this model is robust across age groups (not only university or high school students but also younger children) and across cultures, for example, Chinese students from Hong Kong (Marsh et al., 2002) and students from East and West Germany at the fall of the Berlin Wall (Marsh and Köller, 2003).

Importance of Multidimensionality and Positive Psychology

With respect to the debate on the significance of self-concept in positive psychology, the importance of considering the multidimensional characteristic of self-concept again becomes apparent. In particular, the recent emphasis on positive psychology has tended to advocate that positive self-belief or self-evaluations are desirable for maximizing life outcomes. In their reviews, Baumeister et al. (2003, 2005) originally seemed to question whether high self-esteem really leads to better performance, happiness, or a healthier lifestyle, concluding that "[positive] self-esteem per se is not the social panacea that many people hoped it was" (2003: p. 38) and that "efforts to boost people's self-esteem are of little value in fostering academic achievement or preventing undesirable behavior" (2005: p. 84). However, in refuting these inferences, Marsh and Scalas (2010; see also Marsh and Craven, 2006) pointed out that Baumeister et al.'s (2003, 2005) conclusions "were based largely on research studies, statistical methodology, and theoretical conceptualizations of self-concept that are no longer current" (p. 665).

Baumeister et al. (2003, 2005) concentrated on self-esteem and self-concept from a unidimensional perspective, whereas Marsh and Craven (2006) drew on more recent research on an explicitly multidimensional model of self-concept to demonstrate convincingly the benefits of positive academic self-concept. Similarly, in their reanalysis of the US nationally representative Youth in Transition database (five waves of data that span 8 years from Year 10), Marsh and O'Mara (2008) showed strong positive reciprocal effects between academic self-concept and grade point average (GPA). They also showed that besides prior achievement, academic self-concept is the best predictor of long-term educational attainment. This finding contrasted with the earlier analyses by Baumeister et al. (2003, 2005), who found weak and inconsistent relations between global self-concept and achievement. In summary, strong empirical evidence supports the notion that academic self-concept, when taken as a multidimensional construct, positively influences subsequent achievement after controlling for the effects of prior achievement.

Educational Implications

An important implication of the REM is that educational practices and interventions must take reciprocal relations into consideration. Educational practices that rely solely on the skill development model (i.e., focus primarily on improving academic skills without enhancing self-concept) or the self-enhancement model (i.e., foster self-concept alone without improving academic skills) are overly simplistic and their effects will not be long lasting. The most effective interventions should improve academic skills and self-concept simultaneously.

Frame of Reference: The Internal/External Model

For at least two reasons, the self-concepts of different academic domains would be expected to be correlated. First, as discussed earlier, achievements in different domains are often moderately correlated (e.g., achievements in mathematics and the verbal domain are typically correlated at 0.5–0.8; Marsh, 2007), whereas academic achievement in each individual domain is

related to its respective self-concept (e.g., mathematics achievement and mathematics self-concept). Hence, it is logical to expect the self-concepts of different domains (e.g., mathematics and verbal) to be correlated, too. Second, according to the proposed hierarchical structure (Marsh et al., 1988), the self-concepts of academic subjects should share some common variance in order to build up this hierarchical tree structure.

Simultaneous Use of External and Internal Frames

Surprisingly, however, empirical research has shown repeatedly that self-concepts in different academic domains are almost unrelated and sometimes even negatively correlated. This hardly reflects the corresponding relations among academic achievement in different domains and reaffirms the conclusion that domain specificity overrides hierarchical structure. These seemingly paradoxical relations were explained by Marsh (2007) using the internal/external (I/E) model. The model proposes that objective accomplishment (e.g., 80% of items correct in a test) is only one of the determinants of self-concept. Indeed, an individual's self-perception cannot be understood adequately without recognizing the prevailing frame of reference (e.g., how other students perform in the same test). Thus, unless this frame of reference is identical for all students (e.g., 80% correct is considered to be excellent by all students), the self-concepts of students will vary according to the specific reference frames that they have adopted.

The I/E model postulates that students simultaneously use both an external (normative) frame and an internal (ipsative-like) frame in forming their self-concepts. In the former, students compare their performances with external information and criteria such as objective indexes in public examination results and the performances of classmates. On the basis of this external frame, students who perform outstandingly in public examinations or better than their classmates tend to have higher levels of self-concept. In the internal frame, students judge their abilities in one academic subject with reference to their own performance in other subjects. Thus, when two students who have similar verbal examination scores are asked to rate their verbal self-concept, students who perform better in mathematics will tend to have a lower verbal self-concept than those who perform worse in mathematics.

Empirical Evidence

Statistically, if the verbal and mathematics achievements and self-concepts of students are measured, the comparison in the external frame would predict that verbal achievement positively affects verbal self-concept. The greater the verbal achievement of students, the higher are their levels of verbal self-concept (see the strong positive path from verbal achievement to verbal self-concept in Figure 3). Simultaneously, the comparison in the internal frame would predict that mathematics achievement negatively influences verbal self-concept and, similarly, verbal achievement negatively affects mathematics self-concept (the moderately negative crossed paths in Figure 3). Thus, the correlation

Figure 3 Predicted (Panel a) and actual (Panel b) results based on the I/E frame of reference model. In Panel (a), the horizontal (positive) paths are predicted to be substantial and positive (++), whereas the cross (negative) paths are predicted to be smaller and negative (−). In Panel (b), the actual results, which are based on total group analysis and the multiple group analysis, are consistent with the predictions. Reprinted with permission from Marsh, H.W., Hau, K.T., 2004. Explaining paradoxical relations between academic self-concepts and achievements: Cross-cultural generalisability of the internal-external frame of reference predictions across 26 countries. Journal of Educational Psychology 96, 56–67. http://www.apa.org/about/contact/copyright/index.aspx.

between verbal and mathematics self-concepts would be substantially lower than the typically high values of correlation between verbal and mathematics achievements. Depending on the relative strength of the effects of these internal and external comparisons, this correlation would be close to zero, slightly positive, or slightly negative.

The above statistical predictions have been confirmed and supported in a large number of cross-cultural studies, reviews, and meta-analyses (e.g., Marsh and Hau, 2004; Möller et al., 2009). For example, in the large ($N = 55\ 577$) Organisation for Economic Co-operation and Development Program for International Student Assessment (PISA) study, which was composed of nationally representative samples of 15-year-olds from 26 countries (Marsh and Hau, 2004), the horizontal paths from mathematics achievement to mathematics self-concept and verbal achievement to verbal self-concept were highly positive (0.44 and 0.47, respectively; see Figure 3), whereas the two cross-paths, mathematics achievement to verbal self-concept and verbal achievement to mathematics self-concept, were negative (−0.26 and −0.20, respectively). As predicted, the correlation between verbal and mathematics self-concepts (0.10) was substantially smaller than that between verbal and mathematics achievements (0.78). These findings, which were based on the total sample, were replicated in almost all the separate analyses for each of the 26 countries. Thus, the results were

in line with the conclusion of Möller et al.'s (2009) meta-analyses ($N = 125$, 308 from 69 data sets) on the relations between mathematics and verbal achievements and self-concepts.

In summary, although cross-cultural studies (e.g., the PISA study) and meta-analyses have their strengths and limitations (Marsh et al., 2009), the convergent results from both paradigms provide strong support for the I/E model across divergent educational contexts.

Educational Implications

Theoretically, the I/E model demonstrates once again the importance of the multidimensional nature of self-concept in related research. Practically, teachers and parents who infer the self-concepts of students predominantly from external comparisons (e.g., performance in examinations) should also pay attention to the internal frame adopted by the students (Dai, 2002; Marsh and Craven, 1997). For the brightest students in a class, even though their academic achievements might be better than those of their classmates in most subjects, their self-concepts will vary by subject area. For example, among these brightest students, those who are stronger in mathematics and science subjects and slightly weaker in verbal-related subjects might have much higher levels of self-concept and interest in science and mathematics and hence spend more time and effort on these subjects. By contrast, they might not pursue verbal-related subjects to the same extent, even though their objective abilities and demonstrated performances in these subjects are still much better than those of their classmates. Similarly, for the brightest students who are stronger in verbal subjects and weaker in science subjects, it might be difficult to understand their relative lack of interest and low levels of self-concept in science given their outstanding performance (e.g., objective marks) in these subjects relative to their classmates. These phenomena can be interpreted better by recognizing that self-concepts in different domains are highly differentiated and that some students consider themselves to have a greater aptitude at mathematics or verbal-related subjects on the basis of the internal comparison process.

Students who perform poorly value their worth through the internal comparison process in a similar manner. Although their performances in most academic subjects are weaker than those of their classmates, they still have relatively higher levels of self-concept in their better subjects. Therefore, teachers and parents could aim to build academic interest in these weaker students from the platform of their slightly better subjects (in which they show relatively higher levels of self-concept).

Frame of Reference: The Big-Fish-Little-Pond Effect

The big-fish-little-pond effect (BFLPE) cannot be adequately understood if the standards of comparison and the frames of references people use to evaluate themselves are ignored. It derives from "research on adaptation level, psychophysical judgment, social psychology, sociology, social comparison theory, and relative deprivation theory" (Marsh et al., 2008: p. 321; see also Möller and Marsh, 2013), among others. Marsh (1984) proposed the BFLPE model to explain the frame-of-reference effects that result when students compare their own academic performances and abilities with those of their peers. The BFLPE model postulates that students present higher (lower) levels of self-concept when they compare themselves with less (more) able classmates. Consequently, the BFLPE theory posits that for two students of similar ability, the one who attends a school that has a higher average ability presents a lower self-concept than the attendee of a school that has a lower average ability. Statistically, the academic achievements and abilities of students should have a strong and positive effect on their individual self-concepts, whereas the average abilities of their classmates or of the school as a whole (termed class- or school-average achievement) should negatively affect individual self-concept. Given that high-ability students tend to cluster in similar schools, student achievement should also have a positive effect on school-average achievement.

Empirical Evidence

The BFLPE model has been supported empirically in various surveys, experimental studies, and reviews (Marsh, 2007; Marsh et al., 2008). With the development of more appropriate analytical methodologies, the model has also been supported repeatedly by use of the multilevel modeling approach and in a large number of non-Western cultural and educational settings. For example, among the representative samples of students from 26 countries in PISA (Marsh and Hau, 2003), the effect of school-average achievement on individual self-concept was found to be negative in all 26 countries, reaching statistical significance in 24 countries (mean $= -0.20$, standard deviation $= 0.08$; negative in the remaining two countries but not significant). Similarly, in data analyses of the Trends in International Mathematics and Science Study study, school-average achievement was found to affect students' self-concepts negatively (Chiu, 2012). These results further support the generalizability and importance of the BFLPE in diverse settings.

Other Outcomes and Moderators

In PISA, 2003 (OECD, 2004), Seaton et al. (2009) extended the work done by Marsh and Hau (2003) and replicated their results with samples from 41 countries. Nagengast and Marsh (2011, 2012) also examined the BFLPE in PISA, 2006 (OECD, 2007) for the total international sample, the total UK sample, and each of the four UK countries. In particular, they used the more appropriate doubly latent model (vs the multilevel model with a single observed indicator variable at the class/school level) and a less often studied subject (i.e., science). The results supported the general applicability of the BFLPE with respect to science for the international and UK samples. Importantly, among the 57 countries examined, they found that (1) students' individual achievements were positively related to self-concept (52 countries) and career aspirations (42 countries), (2) the positive effect on career aspirations was mediated through self-concept (54 countries), and

(3) the effect of school-average achievement (BFLPE) on self-concept (50 countries) and career aspirations (31 countries) was negative (Nagengast and Marsh, 2011, 2012). These results attested to the generalizability of the negative effects of the BFLPE and their importance in mediating career aspirations across diverse educational settings.

Indeed, the negative effects of school-average achievement can be profound and long lasting. Marsh (1991) analyzed the High School and Beyond data on 1000 randomly selected high schools in the United States and approximately 30 randomly selected students from each school. This longitudinal study showed that the school-average achievement negatively affected academic self-concept, educational aspirations, general self-concept, coursework selection (e.g., selecting less demanding coursework), school grades, standardized test scores, occupational aspirations, and subsequent attendance at college. Moreover, some of these negative effects continued for at least 2 years after high school graduation and they were significant even after controlling for the effects of intermediate variables for the sophomore or senior year at high school. This finding suggested that the effects of school-average achievement (BFLPE) were negative beyond the already negative effects of the sophomore year at high school, suggesting that the BFLPE is long lasting.

Researchers have also investigated the potential mediators of the BFLPE (Marsh et al., 2011) in order to identify the contextual variables (e.g., classroom atmosphere) or individual differences (e.g., achievement goals) that might counteract or reduce the negative effects of the BFLPE. For example, studies have examined whether the BFLPE would have a negative effect on students of all levels of ability. Statistically, this is equivalent to testing the interaction effect between school-average achievement (i.e., BFLPE) and individual students' abilities (or other variables). However, in general, research does not support this interaction (Marsh and Hau, 2003; Marsh et al., 2011), and the BFLPE has been shown to be consistently negative across all achievement levels and all countries (e.g., all 26 countries in PISA, Marsh and Hau, 2003). In PISA 2003, Seaton et al. (2010; see also Marsh et al., 2008) also examined a wide range of potential moderators (ability, socioeconomic status, learning style, elaboration, memorization, control strategies, extrinsic motivation, intrinsic motivation, self-efficacy, anxiety, competitive preferences, cooperative learning preferences, identification with school, attitudes to school, sense of belonging, student–teacher relations), but found that these interactions were either not significant or of no substantive importance.

Mechanism of the BFLPE

Those who are skeptical about the negative effects of school-average achievement might argue that this shortcoming is only a temporary disadvantage because of grading-on-a-curve practices. In other words, all schools, irrespective of how well or poorly their students perform, award similar distributions of high and low grades to their students (i.e., all schools have similar GPA distributions). For two students who have similar abilities (as measured by public examinations), the one who studies in a competitive school would receive lower school grades and hence have a lower self-concept than the student who attends a school that has a lower school-average achievement.

The effect of school grades, independent of the contribution of school-average achievement, has been examined in various empirical studies (Marsh, 1987; Marsh and Rowe, 1996; Trautwein et al., 2006). This research has demonstrated that although school grades do partially explain and contribute toward the BFLPE, the negative effects of school-average achievement persist in addition to the effect of school grades. Reviews have also shown that these effects remain stable over time – even years after graduation (e.g., Marsh et al., 2007, 2008). For example, Marsh and O'Mara (2010) found that in a representative US sample (followed from Grade 10 to 5 years after high school graduation), the effects of the BFLPE due to school-average ability on academic self-concept, school grades, and educational and occupational aspirations were negative and that these were partially mediated through self-concept on distal outcomes.

Theoretically, there are two counterbalancing effects in attending a school that presents a high school-average achievement. On one hand, attending such schools should boost students' levels of self-concept, because the so-called assimilation effect will be positive (i.e., the 'reflected glory effect'). On the other hand, students in prestigious schools endure constant competition and comparison with high-ability classmates and schoolmates. This 'social comparison effect' is often negative. Thus, the BFLPE is the sum of these two counteracting effects and in general is negative. Given that the BFLPE has been found to be consistently negative across studies and countries, the negative effects of social comparison must be greater than the positive effects of reflected glory across a wide spectrum of educational settings. Indeed, Marsh et al. (2000) demonstrated empirically that when the positive reflected glory effect from attending a high-achieving school is removed, the negative effects of social comparison are much more negative than the generally documented overall BFLPE.

Experimentally, a negative BFLPE due to high school-average achievement can also be demonstrated by comparing the effects that arise from intergroup (positive social glory by comparison with lower average achievement schools) and intragroup (negative social comparison with high-ability classmates) comparisons. Zell and Alicke (2009) manipulated the standards of comparison in a series of studies and demonstrated that the overwhelmed negative intragroup comparisons are the main source of students' self-evaluation.

Educational Implications

Parents, teachers, and students might have believed naively in the benefits that attending a high-achieving school might confer on students' levels of self-concept and achievement, while forgetting that these students might actually begin with higher levels of achievement. When these prior differences are controlled for, students in these schools might actually suffer from the constant negative social

comparisons with classmates. Consequently, teachers in prestigious schools might need to consider deemphasizing intraclass competition and stressing individual growth, progression (comparison with self), or external objective standards. At the very least, teachers and parents should be aware of the potential negative impact on students' self-concept when they attend competitive and elite schools.

The BFLPE can be extended to the two extreme groups with respect to ability, namely, gifted-and-talented classes at the high end and inclusion classes at the low end. Grouping gifted-and-talented students in the same class might lead to a decline in self-concept (i.e., compared with that of similarly gifted students in mixed ability groups) due to the social comparison effect (Marsh et al., 1995). The labeling theory suggests that the self-concept of students who have a learning disadvantage could be hampered if they are placed in special classes with similarly disadvantaged students, a main argument for the inclusive education movement. According to the BFLPE, students with a learning disadvantage would have relatively low levels of self-concept in regular mixed ability classes (i.e., compared with that of similar ability students in special classes for disadvantaged students) because of constant social comparisons with higher ability students. Indeed, empirical evidence for children who have a learning disadvantage and are in mainstream and support classes suggests that the negative BFLPE from social comparison is stronger than the positive benefits of studying in regular classes (Tracey et al., 2003; Marsh et al., 2006a). Research has shown that learning-disadvantaged students in mainstream classes have significantly lower academic self-concepts than their counterparts in special classes, which thus argues against the applicability of labeling theory to the self-concept of learning-disadvantaged students in this kind of mainstream schooling.

Although the above findings do not mean that the movement for inclusive education should be disbanded, teachers and parents should be aware of the potentially negative effects of social comparison when disadvantaged students are placed in mainstream classes. If policy makers decide to adopt mainstreaming, it might be necessary to exert additional effort to reduce the potentially negative effects on students' self-concept, for example, by minimizing intraclass comparisons. Similarly, it is necessary to be equally cautious when segregating gifted-and-talented students into special classes or segregating students by ability within schools (i.e., tracking, see Hattie, 2002), which might reduce rather than enhance students' self-concept.

As shown earlier, the BFLPE is consistent and relatively unaffected by other potential mediators (Marsh et al., 2011; Seaton et al., 2010). The discouraging implication of this fact is that teachers might have little ability to reduce the negative effects of the BFLPE (e.g., creating a cooperative rather than a competitive classroom atmosphere, hoping to reduce the negative BFLPE). If teachers find that the negative BFLPE is having a damaging effect on ability-tracked classes, it is likely that changing to a mixed ability class structure will be more effective than attempting drastic measures to alter classroom culture, such as moving toward ability-segregated classes.

Summary and Conclusion

The results from the multitude of previous empirical studies on self-concept have helped to support, refine, and advance the theories on which such studies were built. Importantly, domain-specific self-concept rather than general self-esteem has been demonstrated and is theorized to be more useful in the interpretation and understanding of various psychological constructs. Interventions such as improving the verbal competencies of students through enhancement of their self-concept must take account of the multidimensional characteristic of self-concept. Further, it is necessary to work on specific domains of self-concept rather than apply traditional enhancement strategies to general self-concept. Similarly, according to the REM, educational interventions must focus on both improving students' levels of achievement and enhancing self-concept in order to be effective and long lasting.

The present article has demonstrated the successful synergy and interplay between theory building and empirical research. The development of instruments and the design of relevant empirical studies can now be based on strong theoretical models. These empirical studies are substantive, theoretically important, and relevant to policy makers because they are grounded on strong theories. In turn, the findings from these studies support the revision and refinement of the theories. Therefore, this methodological/substantive synergy offers crucial construct validity for any research project (Marsh et al., 2006). The research on self-concept demonstrates the successful interplay among the inextricably intertwined notions of instrument development, empirical research, and theory building.

Access: Geographical

Emily Talen, Arizona State University, Tempe, AZ, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Access in a geographical context is the quality of having interaction with, or passage to, a particular good, service, facility, or other phenomenon that exists in the spatiotemporal world. Access is a relative concept that varies according to the level of opportunity afforded and in the sense that assessments of access (or lack of access) are made meaningful by comparing access in one zone (or for one type of individual) to access in (or for) another. If goods are spatially specific, geographical access typically involves one or more origins and one or more destinations and the distance between them. Emerging definitions of access are concerned with the role of information technologies, environmental justice issues, and normative views. The role of access in defining spatial equity is also paramount. Measurement of access involves not only the characteristics of origins and destinations, but characteristics of the travel mode and route between them. Also, the characteristics of the individual seeking access affect how access is measured. Accessibility is measured in a variety of ways, and there can be significant variation in the resulting measurement depending on the method used.

Definition and Meaning

Access in a geographical context is the quality of having interaction with, or passage to, a particular good, service, facility, or other phenomenon that exists in the spatiotemporal world. For example, access may be based on measuring the distance or travel time between where residents live (housing units) and the facilities they need (e.g., medical facilities, shops, workplaces). Access is also a relative concept that varies according to the level of opportunity afforded at the destination. Assessments of access (or lack of access) are made meaningful by comparing access in one zone (or for one type of individual) with access in (or for) another. If goods are spatially specific, geographical access typically involves one or more origins and one or more destinations and the distance between them.

Alternative Definitions

While the above definition of access is common, other concepts of access are gaining importance. One emerging view is that the notion of access must be redefined for the information age, whereby transactions take place in virtual as opposed to physical space or some hybrid form. Part of this interest relates to the notion of varying levels of access to information technologies and how this variation affects matters of equity in a wide variety of ways. But there is also an attempt to understand how information technology has changed accessibility patterns by changing the geographic locations of people and the built environment that sustains them. If information technologies affect patterns of land use, for example, such technologies indirectly affect accessibility patterns that are determined by land use configurations. Another complexity is that access does not have to be viewed as a positive phenomenon. Access to goods can also be negative, as in the case of environmentally hazardous areas, dilapidated buildings, or other services and facilities viewed as having negative externalities. When these negative costs associated with access are analyzed, the issue is one of environmental justice and whether there are discriminatory patterns of negative access along racial or economic lines. Studies have shown that access to negative conditions in the environment is often higher among low-income groups (Bowen et al., 1995).

Some views of access are not based on distances between two or more locations in space, but may instead be based on social factors, cultural barriers, or ineffective design. For example, barriers to access may be based on whether or not an individual possesses a certain subjectively defined level of 'citizenship' (Staeheli and Thompson, 1997). In addition to exclusionary practices that prohibit certain groups from 'free' access to a given good, problems inherent to the good, service, or place itself can affect access. For example, public parks may or may not be designed appropriately to deter crime by incorporating defensible space techniques, which in turn may significantly affect access to that space.

Spatial Equity and Access

Access defined on the basis of spatial distributions invokes the concept of spatial equity. The issue is one of who has access to a particular good or service and who does not, and whether there is any pattern to these varying levels of access. Spatial equity can be defined as equality, in which everyone receives the same public benefit (i.e., access), regardless of socioeconomic status, willingness to pay, or other criteria. Alternatively, access equity may vary according to indicators such as poverty, race, or the nature of the service being provided.

In a distance-based analysis, the goal might be to determine if access to a particular good is discriminatory. Such inquiries might entail, more specifically, detecting whether there is a spatial pattern to varying levels of access, and whether that spatial pattern varies according to spatially defined socioeconomic groups (Talen, 1998). For example, do people of minorities have to travel further to gain access to public goods than do others?

An overview by Marsh and Schilling (1994) on the measurement of equity in facility location analysis lists the contributions of political scientists, sociologists, economists, geographers, and management scientists. Many divergent modes

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72002-2

of analysis are discernible. Health-care professionals are often interested in the degree to which access to health care is properly distributed not only to prevent health crises, but to ensure that overall population health is maintained (Guagliardo, 2004).

Access based on need is a matter of matching resources and facilities to target populations. Examples include matching HIV service providers to target populations (Fulcher and Kaukinen, 2005), or connecting food supermarkets to socially deprived areas, or those who could benefit most from having access to food retailers (Apparicio et al., 2007). Savannah, Georgia has analyzed spatial access to facilities to direct city resources into the neighborhoods judged to be 'the worst off' (Toulmin, 1988). Health organizations are often involved, participating in 'mapping audits' of health service provision, now made easy through the use of geographic information systems (GIS). Higgs (2004) reviewed the use of GIS-based measures of access to health care among government entities intent on increasing a 'social justice policy agenda' (p. 119).

In addition to exposing differentials in accessibility, research seeks to discover why certain patterns of access exist. Factors implicated include urban form, organizational rules, citizen contacts, politics, and race. Until recently, spatial inequity has been explained predominantly by the notion of unpatterned inequality (Mladenka, 1980). This is the idea that although inequality in people's access to services and facilities exists, no evidence of a clear discriminatory pattern can be found. In the absence of patterned inequality, some argue, it is difficult to attach blame to those responsible for the existing distributional pattern. Some critiques of this theory (Miranda and Tunyavong, 1994) focus on the failure to take the political process properly into account as well as the problem of variable definition.

The complexities involved in the equitable access of public resources include not only methodology (how can equitable access be measured?), but also a multitude of value judgments about who should benefit, the nature of social justice, and the definition of political consensus. Measures have become more and more complex and nuanced, for example, in the application of indices of 'relative well-being' that are thought to more carefully account for inequalities (Albrecht and Ramasubramanian, 2004: p. 371). The stakes are high: since public resources are, in some sense, part of each individual's income, their spatial distribution directly affects the distribution of public welfare (Pahl, 1971; Harvey, 1973).

Distribution (access) based on demand is a matter of surveying the spatial distributions of specific kinds of facilities and matching those distributions to the specific populations who need access to them. For example, a study of access to the services needed by public housing residents, based on mapping levels of demand and need, concluded that almost half of public housing residents were not having their demands met (Apparicio and Seguin, 2006).

Normative Views of Access

Related to equity considerations, the concept of access has taken on a normative role. Accessibility has been a long-standing component of theories of good urban form (see in particular Jacobs, 1961; Lynch, 1981; Jacobs and Appleyard, 1987). Kevin Lynch (1981) held access as a key component of his theory of ideal urban form and argued that access could be used as a measure of 'settlement performance' by factoring in (1) the feature to which access is being given; and (2) the person receiving access. Increasing access to needed facilities, goods, and services among low-income populations is considered to be an essential part of social policy. The 'geography of opportunity', significantly influences the ability of low-income residents to improve their lives (Briggs, 2005). It is also understood that for locally oriented populations – residents who rely on modes of transport other than the automobile (e.g., the elderly and the poor) – accessibility to urban services may be more important because distance is not elastic (Wekerle, 1985).

Elevating the role of geographical access is closely tied to the view that settlement patterns should increase access between residents, their places of work, and the services they require. In this regard, accessibility is not conceptualized as an issue of private mobility but is generally approached as a community-wide, public problem. Equity in accessibility to resources is therefore tied to the principles of smart growth (Song and Knaap, 2004) and active living environments (Heath et al., 2006; Norman et al., 2006) in which pedestrian access to daily life needs is viewed as especially important. In this same genre, New Urbanists have developed a specific town-planning manifesto based on enhancing access at the level of region (by promoting a variety of transportation alternatives), metropolis (by promoting compact urban form), and neighborhood (by promoting mixed uses and housing density).

Of course, other factors challenge the idea that accessibility is a crucial goal. Notably, there is recognition of the fact that physical distance is lessening in importance, technology is obfuscating the need for centered settlements, and low-density dispersed development is merely the inevitable outcome of the post-Fordist urbanization process (Bruegmann, 2005). With the emphasis on information technology and digital methods of social connection, the idea of access may be downplayed as tangential, despite the importance of pedestrian-oriented access for those who lack mobility (the elderly and disabled, the poor, working parents). Downplaying physical access may mean that access is not deemed relevant or that market forces are deemed too difficult to overcome. In practice, the role of accessibility in transportation planning might be reframed as congestion reduction or efficiency. Others might frame the issue as one of increasing people's land use and transportation choices (Levine, 1998), or emphasizing that changes to transportation systems have profound consequences for environmental justice (Chakraborty et al., 1999).

The Measurement of Access

The majority of studies of geographic access assume that access is a positive phenomenon, and that access is based in part on some measurement of distance in space. If access is being considered as something desirable, the impediments to access – friction or blockage of the opportunity to interact or the right to enter – must be factored in. Right of entry assumes that a transaction must occur between the consumer and the good, service, or facility. More important in terms of definitions of access is that these transactions have a cost associated

with them. Geographical interest in access therefore is often focused on these transaction costs. The interest is often methodological – how can transaction costs be measured? Empirical investigations focusing on, for example, who pays a higher transaction cost for access and why invoke the issue of spatial equity discussed above.

Factors Affecting the Measure of Access

Five classes of factors affect the measure of access. The first two are simply the spatial locations of points of origin and points of destination. Usually, the points of origin refer to housing locations and points of destination involve entities that can be spatially referenced, such as schools or places of employment.

The third factor is the travel route and its distance between an origin(s) and destination(s). This involves not only the distance between two or more points, but the qualities of the route and the mode of travel that occurs on that route. Route factors include topography, design speed, number of lanes of traffic, and mode. For pedestrian access, perceived safety, sidewalk quality, and traffic volumes are important. Measuring the distance along a route can be based on the shortest distance between destination and origin, or can be more complex and involve a variety of spatial networks.

Another factor affecting the measurement of access has to do with the attributes of the people who seek access; these characteristics are usually measured for spatial aggregations such as a census tract or census block (the degree of disaggregation of the spatial unit varies widely). Factors that might affect access include socioeconomic status, age, gender, and employment status. Certain assumptions can be made about the attractiveness or relevance of travel to certain facilities (and the likely mode of travel) based on these characteristics. The frictional effect of the available travel mode is also likely to be predicated on the characteristics of residents. For example, lack of bus service may adversely affect access for low-income individuals but have only a marginal impact on high-income groups.

A final class of factors concerns the size, type, and quality of the destination (e.g., facility). These attributes determine the attractiveness of a destination for consumers and therefore affect how access to it is measured.

Types of Measures

Accessibility can be measured in a variety of ways. At one end of the spectrum, accessibility measures can be based on random utility theory, where access is based on the desirability or utility of a set of destination choices for an individual (Handy and Niemeier, 1997). Another similar approach uses travel diaries of individuals to estimate 'personal accessibility', based on daily movement patterns (Kwan, 1999). At the other end of the spectrum, accessibility is characteristic of place. Ultimately, how access is measured should be based on how the measure is to be used. For the visualization of spatial equity, it may make sense to focus on the measurement of 'place-based' accessibility – a measure that serves as a characteristic of a place. This conceptualization of access carries with it a number of variations.

One of the most widely used measurement methods is known as the 'container' approach, which is simply a count of the number of facilities within a given area such as a census tract, political district, or municipal boundary. Alternatively, a 'minimum distance' approach measures access as the distance to the nearest facility (often used in research on access to health-care services), whereas the 'travel cost' approach calculates the distance (cost) between an origin and all included destinations (often the preferred method for calculating access to amenities such as parks within a city). Using the basic idea of 'proximity as a measure of access', Lindsey et al. (2001) looked at the equality of access between urban greenways and populations groups, finding that 'minorities and the poor have disproportionate access to trails'.

Another option is to use the gravity 'potential' measure, where facilities are weighted by their size (or other characteristic) and adjusted for the frictional effect of distance. Pacione (1989) examined differences in access to secondary schools by compiling mapped indices of access using a gravity-based model, which revealed different 'undulating' surfaces that could be used as a basis for comparing the effects of school closings on access. In addition to visual comparison of spatial variation, Pacione derived an overall coefficient of variation, by which the aggregate effect on the overall access of different spatial patterns of facilities can be compared. The socioeconomic characteristics of the neighborhoods that fared better and those that fared worse, in terms of facility provision, were presented to reveal any underlying patterns of distributional bias. Geertman and Ritsema Van Eck (1995) also showed how to produce maps of 'potential surfaces', using the gravity potential method of measuring accessibility. Although socioeconomic variables were not included, the authors showed how the maps can be used to visually identify, for example, potential building sites with adequate public transport.

Some researchers have compared the results of using multiple access measures. Brabyn and Gower (2004), for example, compared the ratio, least-cost path, and allocation methods to determine how the interpretation of access to medical providers changes. Luo and Wang (2003) synthesized two accessibility measures, a gravity-based method and a floating catchment area method, to analyze accessibility to health care in a GIS-based visual assessment.

A primary question is what characterization of access is most suitable? Largely, the answer depends on how best to characterize distance between the user and the facility. If evaluating access to amenities, the value of the facility to the user declines with distance. If the analysis concerns emphasizing the effect of distance as a deterrent, then the gravity model may be appropriate. Alternatively, it may be appropriate to compare access to facilities as an average of all distances to all facilities (travel cost measure), which treats the resources of a city as a complete package of public goods. If the goal is to assess how to minimize the inequality of nearest distance between origin and destination, then a minimum distance measure is appropriate. Finally, if the goal is to maximize the number of people 'covered', and if it is decided that beyond a given radius, users acquire no benefit, then a covering approach may be warranted.

If the purpose of access measurement is to determine neighborhood service provision, 'covering' and 'minimum distance' are probably the most appropriate. This is because

access at that scale essentially revolves around two concepts of access: how far does one have to walk to reach a destination, and how many urban opportunities are within walking distance? For the first question, minimum distance is measured between some point of origin (such as a census block centroid) and the point location (street address) of the given facility. For the second question, a covering radius is drawn around the point of origin, and the number of facilities within, for example, walking distance, is determined.

For each measurement approach, a number of different measurement factors have to be considered. First, points of origin have to be selected; these could be point locations of individual housing units on a parcel or the centroids of larger geographic units (e.g., census blocks, block groups, or tracts). An obvious issue in this selection is the potential introduction of aggregation error that results when a single point is chosen to represent an entire area. At a minimum, researchers will need to address the problem of ecological fallacy and the modifiable areal unit problem. Hewko et al. (2002) looked at spatial accessibility for neighborhoods and found that the measures used were 'susceptible to numerous methodological problems' (p. 1185), particularly when the amenity being investigated had many locations.

Another measurement issue concerns population characteristics. If the goal of an accessibility study is social equity analysis, analysts will want to consider the socioeconomic characteristics of a population, since such information allows some assumptions to be made about level of need and travel mode availability. For example, it is likely that residents in poorer areas are more dependent on public transit, have lower access to private automobiles, and therefore require greater access than do residents of high-income areas. Even though distance is the most critical factor in determinations of access one must recognize that in low-income areas distance is more difficult for residents to overcome and lower levels of accessibility are likely to be particularly detrimental.

Acculturation

David L Sam, University of Bergen, Bergen, Norway

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A 1936 definition of acculturation serves as the point of departure in discussing the concept of acculturation. Psychological acculturation (as individual-level phenomenon) is the main focus of the article. Three main theoretical perspectives that define the field are presented. The article also looks at acculturation as a process (focusing on acculturation strategies), as an outcome (focusing on psychological and sociocultural adaptations), and as the relationship between processes and outcomes. Future directions of the field are identified.

Acculturation as a concept encompasses all the changes that occur when individuals and groups of people belonging to different cultural backgrounds come into contact with each other. The term is commonly used when discussing what happens to immigrants, refugees, and ethnocultural groups (particularly so-called ethnic minorities) when they come to live in another society. In recent years, the term has acquired several meanings as it has become associated with concepts such as *globalization*, *multiculturalism*, *integration*, and *assimilation*. While acculturation is closely related to these concepts (see Sam and Berry, 2006 for a discussion), they should not be confused with them.

Powell (1883) is suggested to have been the first to use the term 'acculturation' in the English language in the 1880s, to refer to psychological changes arising from cross-cultural interactions. McGee (1898) referred to acculturation as the process of exchange and mutual improvement by which societies advanced from savagery, through to barbarism and civilization, to enlightenment. Simons (1901), on the other hand, considered acculturation to be a two-way process of reciprocal accommodation, and equated acculturation to the term assimilation. Assimilation was defined as the process of adjustment or accommodation that occurs between the members of two different races. To avoid the different use of the term, and to enhance theory development and research, the Social Science Research Council of the United States set up a committee in the 1930s to analyze and define the parameters for acculturation as a field of inquiry within cultural anthropology. The work of this committee resulted in defining acculturation as

> those phenomena which result when groups of individuals having different cultures come into continuous first-hand contact, with subsequent changes in the original culture patterns of either or both groups…under this definition acculturation is to be distinguished from cultural change, of which it is but one aspect, and assimilation, which is at times a phase of acculturation. (Redfield et al., 1936: pp. 149–152)

This definition, in spite of its age, is still useful, as it points to a number of issues central to the concept.

Some Central Issues to the Concept

Mutuality of Influence

The expression 'changes in the original culture patterns of either or both groups' in the above definition entails *mutual* or *reciprocal* influences, which imply that both groups influence each other. However, due to power differences (such as economic power, or numerical strength), one group often exerts more influence than the other. Often times, there is a dominant group exerting more influence than another, which is less dominant. This has resulted in the assumption that only the nondominant group undergoes acculturation, and has contributed to the rise of the term *ethnic minority*. The assumption that acculturation involves changes only among ethnic minorities has also contributed to a one-sided view of acculturation, and an abundance of research on changes taking place in nondominant groups.

Continuous First-Hand Contact

Continuous first-hand contact as part of the above definition was meant to encompass such complex interactions as a foreign power colonizing another sovereign country and forcing its rule and way of life on the people colonized, to the somewhat benign situations such as living next door to a foreign national (over a prolonged period). The definition from 1936 did not factor in the rapid development in information technology, and the rise of electronic social networks, which in no doubt affect people's behavior. To what extent should virtual interactions between people who live thousands of kilometers away be considered as acculturation? This is clearly an uncharted area that deserves research attention.

Group versus Individual-Level Phenomenon

Although acculturation as a concept was first proposed as a group-level phenomenon, it was also recognized as an individual-level phenomenon. Graves (1967) coined the term psychological acculturation, which has been defined as "the changes an individual experiences as a result of being in contact with other cultures, or participating in the acculturation that one's cultural or ethnic group is

undergoing" (Berry, 1990: p. 203). A distinction between acculturation as a group-level phenomenon and acculturation as an individual-level phenomenon is important; the kinds of changes that take place at the two levels tend to be different. Moreover, not every group or individual enters into, participates in, or changes in the same way during acculturation. Vast individual differences in psychological acculturation exist, even among individuals who have the same cultural origin and reside in the same acculturative context.

Change

Change is central to acculturation and inherent in change are the notions of *process*, which is dynamic, and *an outcome* that may be relatively stable. These two notions underscore that acculturation research and theory are concerned with *how* change comes about, what changes, and the extent of the change, during acculturation (Berry et al., 2006). While cross-sectional studies may be suitable when addressing 'what changes' and the 'extent of change,' they may be insufficient when dealing with how changes come about. Longitudinal studies may be better suited when dealing with the *how* question.

Until the 1970s, acculturation researchers assumed acculturation took place along a single dimension (one-dimensional view), and this ranged from a preference for fully remaining as a member of one's heritage culture, through to becoming a full member of the dominant society. The one-dimensional view also assumed that one could not be fully embedded in the two cultures in contact; the more one was embedded in his or her heritage culture, the less one could be embedded in the new culture, and vice versa.

In contrast, Berry (1974) proposed that acculturation occurred along two independent cultures (a bidimensional view), which presently dominate the field. However, there are some ambiguities regarding how the two dimensions should be operationalized. According to Berry, the two dimensions are (1) the degree to which people wish to maintain their heritage cultures and identities, and (2) the degree to which people partake in the larger society, and interact with others. Research has identified different ways the second dimension has been operationalized. This has included identification with the larger society; as adoption of the national culture; and as adapting to the larger society. Snauwaert et al. (2003) found that an individual's preference for a particular way of acculturating (referred to as acculturation strategy) varied very much depending on how the second dimension was operationalized.

Framework and Theoretical Perspectives

A framework outlining the links between group- and individual-level acculturation has been proposed by Berry et al. (2011), which argues that any comprehensive study of acculturation needs to take into consideration key features of the two original cultures (depicted as Culture A and Culture B in **Figure 1**) prior to coming into contact with each other. Acculturating individuals and groups bring cultural and psychological qualities with them to the new society, and the new society also has a variety of such qualities. The compatibility in cultural values, norms, attitudes, etc. between the two cultural communities in contact needs to be examined as a basis for understanding the acculturation process that is set in motion. Equally important is the nature of the contact relationships between the two groups, whether it is based on domination of one group over the other, on mutual respect or hostility. There is also the need to understand the resulting cultural changes in both groups that emerge during acculturation. The psychological changes individuals undergo and how they adapt to the new situation

Figure 1 Framework for conceptualizing and studying psychological acculturation.

is also important to look at. Identifying these changes requires sampling a population and studying individuals who are variably involved in the process of acculturation. These changes range from simple behavioral changes (e.g., in ways of speaking, dressing, and eating); cognitive reorganization in terms of how they identify themselves and categorize the individuals and groups they interact with to more problematic outcomes, producing acculturative stress as manifested by uncertainty, anxiety, and depression. These changes at the individual level roughly correspond to what has been referred to as the ABCs of acculturation. Individuals then adapt to these changes, psychologically (e.g., sense of well-being) and/or socioculturally (e.g., acquiring the social skills for daily living).

The ABCs of Acculturation

The ABCs of acculturation is an acronym that refers to the three areas of human life that undergo psychological acculturation, namely, affective, behavioral, and cognitive aspects of acculturation (Ward, 2001). The ABCs are in turn, respectively, linked to different theoretical perspectives that dominate the field: a stress and coping theoretical framework, a culture learning approach, and a social-identification orientation to acculturation.

Affective Changes

Although Oberg's work on culture shock may be seen as the start of affective perspectives, the work of Berry on *acculturative stress* epitomizes these perspectives (see Sam and Berry, 2006). Affective perspectives emphasize the emotional aspects of acculturation and focus on such issues as psychological well-being and life satisfaction. This perspective was inspired by Lazarus and Folkman's stress model where acculturation is likened to a set of major life events that may pose challenges to the individual. These life events may qualify as stressors and provoke stress reactions in an individual, particularly when the appropriate coping strategies and social supports are lacking. When serious challenges are experienced and are appraised to be problematic because one is unable to deal with them easily, such as simply changing one's behavior (i.e., behavioral changes) then acculturative stress results. Acculturative stress is a stress reaction in response to life events that are rooted in the experience of acculturation. In line with Lazarus's stress model, not all acculturation changes result in acculturative stress because there are a number of moderating and mediating factors (both before and during the acculturation) such as personal characteristics including age and gender, and social support that may influence the perception and interpretation of the acculturation experience.

Behavioral Changes

These changes build on culture learning theory, where the central premise is that people in cultural transitions may lack the necessary skills needed to engage the new culture. This, therefore, could result in difficulties managing the everyday social encounters. To overcome these difficulties, individuals are expected to learn or acquire the culture-specific behavioral skills (such as the language) that are necessary to negotiate this new cultural milieu. Cultural learning approaches to acculturation entail gaining an understanding in intercultural communication styles, including its verbal and nonverbal components, as well as rules, conventions, and norms and their influences on intercultural effectiveness. This approach corresponds to the behavioral changes indicated in **Figure 1**. Arguably, second-language proficiency and communication competence form the core of all cultural learning approaches and ultimately sociocultural adaptation.

Cognitive Changes

These changes within the context of psychological acculturation are concerned with how people process information about their own group (in-group) and about other groups (out-groups), as well as how people identify with these categories. Individuals need to belong to a group in order to secure a sense of well-being. There is also the tendency to put others and oneself into categories, and this helps one to associate (i.e., identify) with certain groups and not others. Furthermore, humans compare the group they belong to with others, and there is a tendency to have a favorable bias toward seeing positive qualities of the group to which one belongs, thereby boosting our self-image. When individuals and groups enter into an acculturation situation, they are often faced with the questions: 'who am I?' and 'to which (ethnocultural) group do I belong?' Dealing with these questions sets into motion a process of (re)defining one's identity as an individual, and as part of the ethnic group one belongs to (i.e., ethnic identity) and that of the larger dominant society in which they now reside (i.e., national identity). There is a large body of literature that examines ethnic identity from developmental (e.g., Phinney, 1990) and from sociopsychological (e.g., Verkyten, 2005) perspectives. A new line of research within the cognitive perspective is the 'bicultural identity integration' (see Benet-Martínez and Haritatos, 2005; Wiley and Deaux, 2011).

Developmental Issues

Although not a clearly defined theoretical perspective in acculturation, these issues have come to the fore in recent years because of concerns about the future of children and adolescents from immigrant families in Western industrialized societies (see Mansten et al., 2012). A central developmental issue is that young immigrants simultaneously undergo acculturation and development (see Motti-Stefanidi et al., 2012), and as such acculturation theories should be more cognizant of how the two types of changes influence and impact each other. The issues and areas often identified as relevant for acculturation, and which could complicate normal developmental changes include cultural identity, development of self, family values, and peer relations. Recurring questions from this line of research include whether there are age differences for accomplishing developmental milestones, whether immigrant youth deal with developmental tasks in the same way as their national

peers, and whether their acculturation experiences have special impact on how they resolve developmental tasks.

Personality and Individual Factors

Psychological acculturation is based on the notion that individuals enter and differentially participate in acculturation. As such, identifying individual factors and how they impact the acculturation process and outcome has been of great interest. Existing research has examined different aspects of demographic factors and personal characteristics of the individual (broadly defined as personality). One goal of these studies has been to identify the 'overseas type' who can readily adjust to new cultural environments, by focusing on how certain characteristics of the individual (e.g., ethnocentric tendencies) affected adjustment. The list of personality traits/types that have been examined with respect to acculturation is long, ranging from attachment styles and the Big Five, through cultural intelligence to locus of control and motivation. The studies on acculturation and personality have yielded mixed results, and the explained variance of personality factors has been generally low. One reason for the mixed findings is a combination of factors ranging from the operationalization of the personality trait/type itself, to the adjustment outcome examined, and of course the ethnicity and type of acculturation person (e.g., sojourner, immigrant, etc.) of interest.

Acculturation Processes: How Do Individuals Acculturate?

The process of acculturation is concerned with how individuals deal with the meeting between their original culture and that of the new society. Working from the perspective that acculturation involves individual and group factors, it is important that factors from both levels are taken into consideration. At the group level, the important issues to consider are the policies and the expectations from the larger society (see below for a brief discussion, see also Azzi et al., 2011), as well as the expectations from the ethnocultural group that the individual belongs to.

At the individual level itself, Berry has identified two issues of importance, namely, the two dimensions discussed above. According to Berry, preferences for the two dimensions lead to the adoption of four different acculturation strategies, which he termed assimilation, integration, separation, and marginalization. Acculturation strategies depend on the extent to which an individual balances attitudes and/or behaviors around the two issues or dimensions (see Figure 2).

Assimilation is the strategy used when individuals do not wish to maintain their cultural identity and seek close interaction with other cultures (or in some cases adopt the cultural values, norms, and traditions of the new society). The separation strategy is defined by individuals who place a high value on holding on to their original culture and avoid interaction with members of the new society. The integration strategy is used by individuals with an interest in maintaining one's original culture while having daily interactions with other groups; there is some degree of cultural integrity maintained, while at the same time they seek, as a member of an ethnocultural group, to participate as an integral part of the larger social network. The marginalization strategy is defined by little possibility or lack of interest in cultural maintenance (often for reasons of enforced cultural loss) and little interest in having relations with others (often for reasons of exclusion or discrimination). The four strategies are illustrated on the left-hand side of Figure 2.

The four strategies are neither static nor end outcomes in themselves. They can change depending on situational factors (e.g., in the wake of the 9/11 attack in the United States, many

Figure 2 Acculturation strategies in ethnocultural groups and the larger society.

Muslims had to redefine their cultural identities). Moreover, individuals may utilize different strategies for different domains of life (e.g., integration in the area of language, separation in the area of intimate relationships, assimilation in the area of food habits, and marginalization in the area of religion). An individual may live with a constellation of different strategies encompassing different domains of life. This complex constellation may explain the generally low internal consistency in acculturation strategy measures. In a cluster analysis involving five intercultural areas of life – acculturation attitudes, cultural identities, language use and proficiency, peer relationships, and family relationship values among over 30 different ethnocultural groups living in 13 different countries – Berry et al. (2006) found support to the notion that acculturating individuals combine different domains of life into four acculturation profiles, which they referred to as national, ethnic, integration, and diffuse, and these roughly corresponded to the four acculturation strategies of assimilation, separation, integration, and marginalization. The term acculturation profile is used because these clusters encapsulated different aspects of intercultural relations, rather than simply attitudes.

The right-hand side of **Figure 2** illustrates the parallel concepts that are often employed when describing the public attitudes and public policies in the larger society (see Sam and Berry, 2006, for full discussion). The right-hand side of the figure suggests that the larger society may have its own expectations of how individuals should acculturate, and these may not always be consistent with the desires of nondominant individuals. Society's expectation of how individuals of the nondominant group should acculturate (i.e., acculturation expectations) has been the basis of a number of theoretical models including the Interactive Acculturation Model (Bourhis et al., 1997; see also Horenczyk et al., 2013 for discussion of these models).

Acculturation Outcomes: How Well Do People Acculturate?

From a cross-cultural psychological perspective, human behavior is an adaptation to ecological and cultural contexts (Berry et al., 2011). As such, a natural and legitimate question to ask is what happens to people's adaptive behavior when their heritage culture is altered, or comes into contact with another one? A more specific question in this regard is *how well* do people adapt to acculturation demands? A concomitant question is whether there is a relationship between *how* people acculturate and *how well* they adapt.

When discussing how well people adapt during acculturation, the interest is on the long-term outcome of acculturation. As portrayed in **Figure 1**, adaptation is not synonymous with acculturation, but a result of acculturation. In the context of acculturation, adaptation is concerned with well-being, communication competence, self-awareness, stress reduction, feelings of acceptance, and culturally skilled behaviors (see Ward, 2001). Within acculturation, Ward (2001) makes a distinction between *psychological* and *sociocultural* adaptation. Psychological adaptation refers to internal phenomenon characterized by 'feeling well.' This form of adaptation is often assessed by lack of psychological problems (e.g., depression and anxiety), presence of well-being such as self-esteem and satisfaction with life. Psychological adaptation is largely concerned with the affective changes to acculturation, and to some extent the cognitive changes as they bother on self-concept and self-definition. Sociocultural adaptation, refers to the degree to which individuals are competent in carrying out their daily lives in their new social and cultural contexts, such as at school, at work, within the larger society, and is characterized by 'doing well.' Studies of sociocultural adaptation have usually focused on the absence of behavior problems, school achievement, job satisfaction, language skills, interpersonal relations, and social competence. Studies within this domain usually focus on the behavioral changes of acculturation.

How well do people acculturate? Do acculturating people adapt equally well, better, or more poorly than some reference group? The basis for comparisons is an important issue when discussing the adaptation of people undergoing acculturation. Should acculturating people be compared with non-acculturating members of one's own ethnic group; other acculturating groups in the new society; or with members of the new and larger society? Should they be assessed against a psychometrically and standardized instrument measuring adaptation? All three reference groups for comparison as well as using a standardized instrument should ideally be utilized simultaneously. But, quite often, information on the comparison reference groups is not available, nor does the standardized instrument provide unbiased scores. Moreover, considering that everyone in contemporary society is undergoing some form of acculturation, so-called nonacculturating groups as a reference group is nothing more than hypothetical. In view of the different possible groups of people that could be used in making comparisons, it is perhaps not surprising that research findings in terms of how well acculturating groups adapt are mixed. Some studies have found good adaptation outcomes (both psychological and sociocultural) with some acculturating groups doing either better or equally well as their national peers in the society of residence (Berry et al., 2006). However, other studies have found poor adaptation outcomes (Young et al., 2010).

Aside from the issue of different reference groups being used when comparing the adaptation of acculturating individuals, mixed findings have also arisen because of differences in operationalization of acculturation itself (e.g., duration of residence and language proficiency as measures of acculturation), and the adaptation outcome of interest (see Koneru et al., 2007; for a review). Adaptation outcomes that have been studied have ranged from simple psychological problems such as anxiety to more serious ones such as schizophrenia; and from positive adaptation outcomes such as satisfaction with life, self-esteem, to negative behavioral problems. Differences in adaptation outcomes warrant not only a systematic literature review but also a meta-analytic estimate of effect sizes in group difference, and strength of association between acculturation variables and outcome.

Although much attention has been directed to psychological and sociocultural adaptation, some research has found links between acculturation and physical health including different forms of cancer and cardiovascular diseases. However, rather than acculturation resulting in poor physical

health, some studies have suggested that immigrants have better physical health, when compared with their non-migrating peers in the society of emigration. It appears that with increasing acculturation (defined in terms of generation), health status 'migrates' or converges toward the national norm. Closely linked to this observation is what has become known as the *immigrant paradox* (Garcia Coll et al., 2012), where immigrants either show better adaptation outcomes than their national peers, or first-generation immigrants reporting better adaptation than their second-generation peers.

Relationship between How People Acculturate and How Well They Adapt

A number of studies have found that the acculturating strategy that people adopt is related to how well they adapt. The most common finding is that the integration strategy is the most adaptive in several settings and is associated with better psychological and sociocultural adaptation. In a meta-analytic study involving over 23 000 participants, Nguyen and Benet-Martínez (2013) found a strong and positive association between the integration strategy (referred to as biculturalism by the authors) and adjustment (both psychological and sociocultural). Analyses also indicated that the association between integration and adaptation was moderated by the way acculturation was assessed, the adaptation domain, and sample characteristics. Stronger integration–adaptation associations were found when acculturation was conceptualized as a bidimensional as opposed to a unidimensional scale. Marginalization has also been found to be the least adaptive outcome in a number of studies (Berry et al., 2006). One possible reason for why integration results in better adaptation outcome is that it entails a form of double competence and the availability of double resources. These competencies come from one's own ethnic and cultural group and from the new and larger society, and these resources double an individual's ability to cope with cultural transitions. In contrast, marginalization entails little competency in and lack of support from any cultural group; hence, the risks of adaptation difficulties are higher.

Ethnic and racial discrimination is one factor that has been found to be detrimental for positive acculturation outcome, and undermines the acculturation process itself. For instance, people who experience high ethnic discrimination are more likely to prefer separation, whereas those experiencing less discrimination prefer integration or assimilation. This phenomenon has been referred to as reciprocity in mutual attitudes, suggesting that if immigrants experience rejection (e.g., through discrimination) from the society of settlement, then they are more likely to reject (members of) the society in return. Similarly, there is evidence that discrimination is often the most powerful predictor of poor psychological and sociocultural adaptation (Berry et al., 2006). Taking this evidence all together, there appears to be a close (triangular) relationship among acculturation strategies, adaptive outcomes, and discrimination. While it is difficult to ascertain causality because of the use of cross-sectional data, using a structural equation modeling Berry et al. (2006) found a good fit to the assumption that discrimination may be a starting point; high discrimination predicts low preference for integration and poor adaptation, whereas integration predicts positive adaptation.

Conclusions

Worldwide migration and globalization together with increased intercultural relationships have catapulted acculturation into an active and an expanding research field in psychology and many social sciences. Although this article has focused largely on the psychology of acculturation, many of the issues discussed are relevant for the other social and behavioral sciences. As a growing field, many of the issues discussed are still in flux, but some patterns of findings are beginning to crystallize. Contrary to early assumptions, assimilation is not the only way, or the ultimate outcome of acculturation. Neither is it the most desired form of acculturation. Much research has suggested that integration is the most preferred way of acculturating, and also has the best long-term outcomes. Nevertheless, research is still needed to fully understand the antecedents to acculturation preferences, and how these antecedent factors interact with the cultural context in which the acculturation is taking place. To date, much of acculturation research is cross-sectional and quasi-experimental in nature, making it difficult to fully ascertain the impact of the multiple factors. The need for experimental and longitudinal studies is in dire need. Considering that acculturation is taking place across the entire world, research findings to date come from Western industrialized countries. Research from China, India, and Russia where large-scale intercultural contacts are taking place, and among sojourners and refugees settled in various regions of Africa, the Gulf States, and West Asia is very much needed to help develop a broader picture of this phenomenon. Finally, there is the need to expand the mutuality of influence from a simple dominant vs. nondominant group relations, but to several mutual influences. Many contemporary societies are made up of several nondominant ethnocultural groups together with a dominant group. As such, acculturating individuals may be influenced by several nondominant groups, and not only one's ethnic group and the dominant group of the society. Moreover, defining one's identity may be more than simply national and ethnic, and may also include religious identification.

Abstract

Social action is a key concept in sociology, and the development of adequate theories that can explain it is a central task. The social sciences suggest very different models of individual behavior without agreeing on a best solution. To understand the controversies and to sketch fruitful pathways, it is helpful to examine the specific role of social action theories within the more general sociological enterprise in more detail and to derive central quality criteria. Against the background of these criteria, a review of influential, traditional 'models of man' reveals the relative advantages and disadvantages of each approach. Major questions are how to deal with this variety of models and how to progress on the front of social action theories.

Theories of Social Action and Their Role in Sociology

Max Weber clearly defined the concept of 'social action' in his classical work 'Economy and Society': "We shall speak of 'action' insofar as the acting individual attaches a subjective meaning to his behavior – be it overt or covert, omission or acquiescence. Action is 'social' insofar as its subjective meaning takes account of the behavior of others and is thereby oriented in its course" (Weber, 1968, p. 4). This definition is commonly shared by sociologists, as is the fact that the concept is of key importance to sociology. Max Weber even regarded it as the constituent subject of the discipline, which is expressed by the sentence preceding the quotation above: "Sociology (…) is a science concerning itself with the interpretive understanding of social action and thereby with a causal explanation of its course and consequences" (Weber, 1968, p. 4). 'Theories of social action,' accordingly, aim at this understanding and explanation and try to answer why certain (types of) actors chose specific alternatives of action.

Superficially, moving theories of social action into the center of sociological interest might seem somewhat questionable: The demarcation of sociology from other social sciences, for example psychology, is usually seen in the fact that it is basically interested in collective phenomena, rather than in the individual actor; in other words, the 'analytical primacy' for a sociologist lies at the macro level (i.e., the level of the society) (Wippler and Lindenberg, 1987). This view has been explicitly expressed by another prominent father of sociological thinking, Emile Durkheim. According to Durkheim, sociology is the science of 'social facts,' which he explicitly viewed as "existing outside the consciousness of the individual" (Durkheim, 1982, p. 51) and "not having the individual as their substratum" (Durkheim, 1982, p. 52).

When it comes to explaining social phenomena, however, the strategy of staying only at the macro level faces at least two severe problems: On the one hand, relations between social phenomena can hardly be regarded as 'sociological laws,' as they are simply not stable enough but are heavily dependent on time- and space-specific conditions (Hedström, 2005). On the other hand, even under well-specified limited conditions, regularities that are stated at the macro level lack a deeper understanding of the underlying mechanisms and leave a black box in any explanatory storyline (Hedström, 2005; Wippler and Lindenberg, 1987). It is here where theories of social action come in. Going down to the micro level and looking at the behavior of individuals can provide the necessary depth and possibly fill this black box. Regularities in social action seem to be more stable and general than those at the macro level, so social action theories can possibly build the 'nomological core' of a sociological explanation. In other words, while the analytical primacy of sociology is at the macro level of the society, there are good reasons to see the 'theoretical primacy' at the micro level of the individual; this is the general position of 'methodological individualism' to which the concept of social action and the striving for social action theories in sociology are intrinsically tied.

These ideas are usually illustrated with the help of the so-called macro–micro–macro scheme (Coleman, 1990; Wippler and Lindenberg, 1987; Hedström and Swedberg, 1998), which allows one to locate the role of social action theories in sociology more closely. Accordingly, any sociological explanation entails three analytically distinct steps. (1) It has to specify how macro-level conditions affect the situation of (typical) individual actors. This macro–micro step is often called the 'logic of the situation,' and the assertions and hypotheses developed in this step are termed 'bridge assumptions.' (2) It has to explain why (typical) individual actors select specific individual actions. This step on the micro level, the 'logic of selection,' is the realm of social action theories. (3) It has to clarify how the actions of typical individual actors interact and give rise to the collective phenomena of interest. This micro–macro step is called the 'logic of transformation' or 'logic of aggregation.'

The reference to the macro–micro–macro model is not only helpful in understanding the specific role of social action theories as one vital step within the more general sociological enterprise, but also crucial for identifying and understanding the more detailed requirements that a social action theory should fulfill in order to be appropriate for sociology (Lindenberg, 1985). Most importantly, it must be able to connect smoothly to the other two steps: the logic of the situation and the logic of transformation. This means, among

others, that the action theory should conveniently allow formulation of bridge hypotheses that link structural conditions to the parameters of actions, without requiring too much knowledge about the individual. The fact that the analytical primacy is on the macro level sets somewhat other priorities for a social action theory appropriate for sociology compared to action theories in a field like psychology, where the analytical primacy is on the micro level (Wippler and Lindenberg, 1987). Nevertheless, social action theories in sociology should certainly not explicitly contradict well-known findings in neighboring disciplines. Thus, in a sense, they can and should be more abstract, but allow one to decrease the level of abstraction if necessary (Lindenberg, 1992). Not least, like all theories, theories of social action should aim for high precision (i.e., information content) and should be well corroborated (Popper, 1959).

Traditional Views on Social Action

In the history of sociological thought, very different views on social action and underlying 'models of man' have been suggested and discussed. Among the most influential are the homo sociologicus, which emerged from Parsons' voluntaristic theory of action, the interpretative paradigm, and the homo economicus of neoclassical economics.

Voluntaristic Theory of Action and Homo Sociologicus

A major milestone in the development of sociological theories of social action is Talcott Parsons' *The Structure of Social Action* (1937), in which he develops his 'voluntaristic theory of action.' This can be understood as an attempt to synthesize ideas on human behavior to be found in the work of various classical sociologists, among them Weber and Durkheim, but also in that of classical economists. The basic elements of Parsons' framework are actors, goals, means, situational conditions, and normative orientations (norms, values, and ideas). Social action should, accordingly, in general be understood as individual actors making decisions about means to achieve goals, whereby the goals and the availability of alternative means are influenced, on the one hand, by situational constraints and, on the other, by values, norms, and ideas that are shaped by processes of internalization and institutionalization.

Accounting for situational conditions and, most importantly, for normative orientations is Parsons' contribution to the logic of the situation. It pays tribute to the legacy of Durkheim and marries his idea of social determination to the methodological individualism of Weber. The fact that, thus, social structure is explicitly integrated into a general model action is certainly a major comparative strength of the 'voluntaristic theory of action.' But there is also a major weakness, which is the lack of information content with respect to the logic of selection. Parsons' focus is clearly on synthesis and conceptualization; his framework does not provide, however, a clear rule for choosing a precise action alternative. The mere reference to values and norms is not sufficient as they tend not to represent coherent systems that give unambiguous advice.

The latter problem is especially visible in the general idea of homo sociologicus, which emerged out of Parsons' work (Dahrendorf, 1968). This model of man underlying structural functionalism assumes that individuals basically act according to internalized expectations that are embedded in systems of social roles. Role conflicts and deviant behavior are only the most obvious difficulties of this view on behavior. When referring to the macro–micro–macro scheme, the more fundamental problem of the homo sociologicus idea is that, in a sense, it tries to relate social structure directly to the actions, neglecting the role of the active and resourceful actor. As a consequence, it seems adequate only under very special and stable conditions (Lindenberg, 1985), and thus it ends up with problems similar to those of a purely macro-theoretical account.

The Interpretative Paradigm

The voluntaristic theory of action has stimulated intensive sociological attention to the problem of finding adequate theories of social action, and homo sociologicus as suggested by structural functionalism has provoked much critique. A very important line of argument has led to the 'interpretative paradigm' (Wilson, 1970), which is intended to be a corrective against the so-called normative paradigm underlying the work of Parsons and Durkheim. The interpretative paradigm can be traced to rather diverse roots, such as European phenomenology (Husserl, 1965; Schütz, 1967) or American pragmatism and behaviorism (Dewey, 1922; Mead, 1934).

The theoretical perspective has been worked out, especially within symbolic interactionism by Herbert Blumer (1969); it targets the passive role of actors in the normative paradigm, in which norms and values seem to treat individuals like puppies on a leash. This general critique crystallizes into two major points. First, homo sociologicus is seen as, at least, severely incomplete, as norms and values only rarely give clear advice for specific actions. Second, and even more importantly, norms and values cannot be understood as externally given by social structure, but they should rather be understood as an endogenous result of the interactions between individual actors.

According to symbolic interactionism, the way that individuals act toward things is fundamentally dependent on the meaning they attribute to them. This meaning is by no means objectively given but must be understood as a subjective accomplishment of the individual actor, an idea that is tellingly described by the famous 'Thomas theorem': "If men define situations as real, they are real in their consequences" (Thomas and Thomas, 1928, p. 572). The meaning results, above all, from permanent social interactions and communications in which symbols and their interpretation play crucial roles. Accordingly, meanings are constantly changing in response to the environment, and interpretation processes are heavily dependent on situational clues.

Symbolic interactionism thus brings the actor back in and emphasizes his or her very active role via processes of interaction and interpretation. In doing so, it contributes specifically to a more adequate and realistic understanding of the definition of the situation. In this attempt, however, the analytical primacy shifts away from the macro level, and correspondingly it is difficult within this approach to develop bridge hypotheses

that link individual interpretations back to social structure; it requires quite a lot of idiosyncratic information about the individual. Moreover, the approach is particularly weak (even weaker than the normative paradigm) with respect to the logic selection: It does not provide clear and information-rich rules about how actors finally choose among different action alternatives.

Neoclassical Economics and Homo Economicus

The theory of behavior used by neoclassical economics has always been a kind of baseline and contrast model against which the sociological search for appropriate social action theories has developed. Basically, homo economicus is assumed to calculate the costs and benefits of available action alternatives and to choose the alternative that best satisfies his or her interests. The underlying core assumptions are thus that social action (1) aims at the realization of preferences, (2) underlies opportunities and restrictions, and (3) is guided by the principle of maximization. These assumptions are seen to constitute the core of so-called rational choice theory (RCT) (Opp, 1999), which comes in a series of more differentiated variants (Goldthorpe, 1998).

Given the inbuilt weaknesses of the genuine sociological approaches sketched here, the economic approach to behavior has also received much attention in sociology. And it has been applied quite successfully: For example, economist Gary Becker received the Nobel Prize in 1992 for proving the microeconomic approach to be extremely fruitful in core sociological fields like discrimination, crime, and the family (Becker, 1976). No less important and impressive, James Coleman demonstrated in his *Foundations of Social Theory* (1990) that RCT can lay the groundwork for a comprehensive treatment of sociology. In general, RCT is one of the most influential theoretical approaches guiding current empirical research in sociology (Kroneberg and Kalter, 2012).

Considering the general criteria for social action theories, RCT provides many comparative advantages: Most importantly, the maximization principle delivers an extremely precise rule of selection, thus overcoming one of the major weaknesses of the normative and interpretative paradigm. It conveniently allows the specification of bridge hypotheses linking action back to social structures, as opportunities and restrictions are crucial parameters of the actor's decision-making process. Viewing actors not only as consumers but also as producers even allows fruitful bridge hypotheses on preferences (Stigler and Becker, 1977). All these aspects foster the main purpose of any explanatory framework, which is to derive precise and testable hypotheses. And all this explains the above-mentioned success of RCT, especially in applied empirical research.

This has led many scholars to the view that homo economicus would in the end best satisfy the needs of explanatory sociology and that the search for alternative models of man might be superfluous and misleading; the term 'economic imperialism' has even been used. The diffusion of RC theorizing in sociology has been likewise accompanied, however, by a growing skepticism: Empirical research has yielded more and more findings that question the core assumptions of RCT (Elster, 1989). Much evidence along these lines stems from experimental research in social psychology, behavioral economics, and behavioral game theory, suggesting that actors are often by no means egoistic maximizers but that behavior is heavily dependent on situational clues, cultural frames, fairness norm, and so on. The evidence that actors thus only show a 'bounded rationality' (Simon, 1957) is overwhelming. Similar doubts on the rational actor model arose from applied research in sociology, with one example being that individuals contribute to the provision of public goods in spite of the incentives of free riding (Opp, 1986). Thus, homo economicus fails to satisfy the basic criterion of delivering an action principle that could claim general validity, and it explicitly contradicts empirical findings in sociology and its neighboring disciplines.

Strategies and Perspectives

The 'Traditional Views' section has shown that the different traditional models of man exhibit different advantages and disadvantages with respect to criteria for an adequate theory of social action. They also emphasize different aspects of human behavior, all of which seem to be indispensable parts of a comprehensive sociological account. This leads back to Max Weber, who in his famous 'Economy and Society' also made a well-known distinction between four main types of social action: action based on instrumentally rational action, value-rational action, affectual action, and traditional action (Weber, 1922, pp. 24–25).

To deal with the different strengths and weaknesses of the different approaches to social action and with the seemingly different types of social action that can be observed in social life, two general strategies can be distinguished: Proponents of a 'pluralistic strategy' claim that sociology simply has to live and work with different models of actors, to keep all of them in a toolbox in peaceful coexistence, and to employ each for different tasks (Schimank, 2000). This, however, remains unsatisfactory for explanatory purposes as long as there is no clear overarching meta-rule specifying exactly under what conditions and for what kind of concrete behavior the one or the other model might be more appropriate; it does not free each of its inbuilt methodological weaknesses, either. Proponents of an 'integrative strategy' therefore seek to work out more refined theories of social action that combine the insights from the different approaches within one overarching model, so that meta-rules are clearly specified and so that the strength of one might heal the weaknesses of the others.

An important development along the integrative line has been the refinement of the narrow model of homo economicus underlying neoclassical economics into 'wide versions of RCT' (Opp, 1999). In particular, these wide versions relax the assumptions that actors are perfectly informed, are purely egoistic, regard only tangible consequences, and react only to objective characteristics of the situation. By allowing, for example, that actors might receive intrinsic utility from fairness, altruism, and compliance to norms, or that they might fear the costs of sanctions, it is possible to marry RCT to many aspects of homo sociologicus. By emphasizing that actors' beliefs are subjective, and can be based on imperfect or even systematically biased information, wide versions of RCT can refute some of the basic objections from the

interpretative paradigm and explicitly account for the importance of processes of interpretation in the logic of a situation. At the same time, however, they keep the main advantage of RCT, which is the clear selection rule. The development from expected value (EV) theory, over expected utility (EU) theory, into the theory of subjective expected utility (SEU) is a major lane in the process of widening (Schoemaker, 1982), and SEU theory has become especially popular in empirical sociological research.

However, the integrative merits and the huge flexibility of wide versions of RCT come at a cost: Releasing the strict assumptions of neoclassical economics leaves the core of the theory almost empty; if everything can in principle be conceptualized as costs and benefits, the theory seems to come close to being a tautology. While this allegation is exaggerated (Opp, 1999), the least one can say, however, is that wide versions of RCT move the explanatory burden from the action theory to the bridge assumptions (i.e., to the auxiliary assumptions made in the step of the logic of the situation, creating new methodological challenges) (Esser, 1998). Consequently, there is widespread skepticism toward 'softening' the RCT approach (Mood, 2009), and there are pleas to stick to narrower versions (if ever, and for as long as possible) (Raub et al., 2011), sometimes leading to an instrumentalist tendency in practice (Hedström, 2005). The 'method of decreasing abstraction' (Lindenberg, 1992) provides a potential recipe in the context of these problems, by emphasizing that it is adequate to work with simplifying assumptions as long as these do not contradict more complex insights and that it must be possible, in principle, to replace the former with the latter if need be.

There are important arguments, however, that even allowing for a much wider range of preferences, expectations, and constraints within RCT might not be enough to enable the necessary theoretical integration, but that a more fundamental revision, touching also – partly at least – its core of the maximization principle, is needed. Accordingly, attempts explicitly try to account for the fact that rationality in actions is conditional and variable. An early example is the contribution by political scientists William H. Riker and Peter C. Ordeshook (1973) to model aspects of bounded rationality in a two-step model, where in the first step actors confronted with information costs decide whether to make a decision at all, thus allowing routines (i.e., 'traditional action' in terms of Max Weber) to take over in many circumstances. Influential two-steps models, in which rational processing is only one possible option, were also suggested in social psychology (Fazio, 1990).

Sociologists working on the front of social action theories have especially tried to bring classical insights about the definition of the situation explicitly and more accurately back into behavioral models. Raymond Boudon (1996) has suggested a 'cognitivist model' that, among others, gives Weber's notion of value-rationality a new fruitful interpretation. Accordingly, actors are often motivated by normative beliefs rather than instrumental incentives, and they are seen to hold these beliefs, because they have good reasons to do so. According to Boudon, this cognitivistic model of action avoids the shortcomings of RCT by providing a more realistic account, at the same time saving RCT's advantage of providing a selection rule within an explanatory framework (Boudon, 1998).

Siegwart Lindenberg (2008) has developed a theory of 'goal-framing' that pays specific attention to the role of situational clues within actions. The basic idea is that actors, rather than considering a wide range of preferences and weighting the corresponding consequences of action (as assumed in traditional RCT), are rather limited and usually regard only one goal that is dominant in a given situation. This goal is in the foreground and mainly frames the definition of the situation (i.e., the attentions, perceptions, and consequently the behavior of actors). Other goals stay in the background, but they might be activated by situational clues and challenge the salience of the dominant 'goal-frame.' Lindenberg identifies some general goals that are shared by all actors, such as the hedonic goal, which is the default in many situations; the gain goal; and the normative goal.

Frames are also the key concept in the 'model of frame selection' that has been brought forward by Hartmut Esser (2009). The model distinguishes several subprocesses in action: 'Mode-selection' determines, as a kind of meta-selection, whether actors behave automatically–spontaneously or reflexively–calculatingly. 'Frame-selection' is crucial to how actors define the situation. 'Script-selection' provides actors with repertoires of action, routines, and programs. 'Action-selection' is the last step. A comparative strength of the model is that it specifies very explicit rules about each of these subprocesses and about how they are interrelated (Kroneberg et al., 2010), thus trying to retain the explanatory power of RCT even while modifying some of its core assumptions. This precision, on the other hand, has made it vulnerable to critique.

In general, these – and other – recent attempts to integrate different lines of sociological thinking about social action are confronted with much skepticism, even more so than against the wide versions of RCT. Many regard these models as much too complex, and especially the concept of frames is suspected to bring black boxes back into explanations (Boudon, 2003). As the analytical primacy of sociology is collective phenomena, the key to the explanation might often lie in the complexity of the aggregation (Hedström, 2005); so one can afford, or is even forced, to work with much more parsimonious models of individual behavior. Proponents of the more complex theories of action would certainly agree, but they would argue that, if necessary, a decrease in abstraction (Lindenberg, 1992) must be possible, and a social action theory must specify in a systematic way how simplifying assumptions, if necessary, can be relaxed.

It is important to recall that whichever kind of simplification or abstractness in the theories of social action is appropriate will always be dependent on the specific explanatory task under consideration.

Actor-Network Theory

Fabian Muniesa, Mines ParisTech, Paris, France

Abstract

This article summarizes some important aspects of actor–network theory. It provides relevant elements of the historical origins of this line of inquiry, examines some of its most distinctive concepts, and signals its development in science and technology studies and in some other areas of the social sciences. The article emphasizes the position of actor–network theory within the poststructuralist landscape, discusses its particular treatment of constructivism, and examines in particular the philosophical implications of the notion of translation, which plays a crucial role in the articulation of this approach.

The social-scientific line of inquiry known as actor–network theory (ANT) is characterized by a distinctively materialist, radically constructivist approach to social theory and to empirical research. It is often recognizable through the use of a collection of notions (such as 'translation' and 'actor–network') that were developed in the 1970s and 1980s in response to developments in the sociology of science. An influential current in science and technology studies, ANT has also gained prominence in a number of different fields in the social sciences and the humanities, from organization studies to political science, from anthropology to economic sociology. In what follows, the historical context of the formation of ANT is first discussed, a series of central concepts are then clarified, and a philosophical assessment is finally suggested (for other relevant accounts see Law, 2009; Mol, 2010).

Intellectual Foundations and Historical Origins

The expression 'actor–network theory' was developed in the late 1980s in order to refer to an emergent school of thought that started to form in Paris, France, a decade earlier. An early mention to an 'actor–network approach' is found in the introduction to an edited volume on the sociology of technology (Bijker et al., 1987). The editors used that expression as a tag to identify and differentiate the approach defended by Michel Callon, who contributed to the volume with a seminal ANT case study on the attempted development of an electric vehicle in France (Callon, 1987). Callon had already proposed a different expression, 'sociology of translation' (*sociologie de la traduction* in French), in order to specify the singularity of this contribution, most notably in another seminal ANT case study on scallop farming along the coast of Brittany (Callon, 1986; see also Callon, 1980). But, in a somewhat path-dependent way, it was the notion of 'actor–network theory' that prevailed in Anglophone academic circles. The intellectual foundations and historical origins of ANT are located in the concrete institutional site of its inception, in the emergence of French poststructuralism and in debates in the sociology of science.

Engineering and Innovation

ANT's origins are to be found in a very concrete location. The approach was crafted at the Centre de Sociologie de l'Innovation (CSI), a small research center at the École des Mines de Paris, an engineering school that is both an elite higher education institution (a so-called *grande école*) and a research institution distinctively oriented toward industrial innovation. The CSI, created in 1967 with the purpose of studying the social determinants of innovation processes, had progressively shifted to a more catholic interest on the interrelations between science and society. Michel Callon, an engineer and sociologist by training and École des Mines alumnus whose earlier research focused on the interfaces between science and industry, was appointed director of the CSI in 1982. The same year, the CSI recruited Bruno Latour, a philosopher by training who was already known for his pioneering ethnography of a neuroendocrinology laboratory (Latour and Woolgar, 1979), a study that prefigured the most salient tenets of ANT's blend of semiotics. The CSI soon became the crucible in which ANT started to take shape. Slightly younger researchers such as Madeleine Akrich and Antoine Hennion, also École des Mines alumni, and visiting scholars such as John Law, then at the University of Keele, participated extensively in the inception of that movement (Susan Leigh Star and Geoffrey Bowker, then at the University of California, were also among the scholars who visited the CSI in the 1980s). Editorial efforts such as *Pandore*, a bulletin that greatly contributed to the diffusion of science and technology studies in France, and exchanges with sociologists and historians of scientific knowledge, notably based in the United Kingdom and the Netherlands, contributed to the shaping of the early orientation of ANT toward the sociology of science.

This localization of the founding of ANT is not accidental. In a sense, the special circumstances that were prompted at the CSI gave ANT some notable characteristics. First, the CSI's intellectual familiarity and daily contact with engineering (in particular in relation to electric systems and extractive industries) translated into a distinctively industrial and technological understanding of constructivism. For ANT, reality is constructed, but it is constructed in the engineer's sense (solid reality as the outcome of an organized, fragile, and laborious process of material articulation) rather than in the sense usually put forward in standard social sciences (social construction considered in terms of social conventions, belief systems, mental states, or collective representations). Second, the CSI's marginal position in the field of instituted social sciences in France and its relative lack of disciplinary control translated into an interdisciplinary (or rather

adisciplinary) attitude. Consequently, ANT questions the boundaries between disciplines and, more profoundly, between the social and the natural sciences, favoring approaches that are able to cope with heterogeneous realities. Third, the tradition of pursuing contract research and developing applied expertise at the CSI, and the combination of highly theoretical developments with extremely practical research reports, translated into a novel preference for hybrid styles. ANT indeed portrays the researcher in general, and the social scientist in particular, as an entangled participant rather than as an external observer viewing reality from above.

Parisian Poststructuralism

The formation of ANT is, in part, an episode in the history of French poststructuralism and a consequence of the intellectual atmosphere prompted in Parisian academic circles by authors such as Michel Serres (see Dosse, 1999; Serres and Latour, 1995). The constructivist approach to science defended by Serres in the 1970s and his distinctive use of the notion of translation played a pivotal role in the intellectual education of early contributors to ANT. The philosophical take on a materialist understanding of signification defended by Gilles Deleuze and the decisive impact that his collaboration with Félix Guattari had on a number of French intellectuals in the 1970s and 1980s was also at work in the emergent repertoire of ANT, especially with their notions of rhizome and collective assemblage of enunciation. The approach to semiotics constructed by Algirdas Julien Greimas (his actantial model in particular) was crucial in the development of ANT's interpretation of the operations of signs and texts. Other notable influences on the formation of ANT can be located in the works of authors such as Michel Foucault, Gilbert Simondon, François Dagognet, André Leroi-Gourhan, and Michel de Certeau, who were widely read at the CSI in the 1980s.

ANT's early development was definitely closer, intellectually speaking, to the philosophical preoccupations broadly associated with poststructuralism, than to other concerns that also characterized French academic life during that period, such as the novel developments in sociology prompted, for example, by Pierre Bourdieu, Alain Touraine, Michel Crozier, or Raymond Boudon, or the issues on complexity and chaos raised in the natural sciences and in mathematics by authors such as Henri Atlan, René Thom, or Ilya Prigogine. The philosophical penchant of ANT was deeply marked by Bruno Latour's own trajectory and vision. The distinctive touch of ANT lay in a taste for a hybrid disciplinary positioning (definitely not as standard social science), an obsession with the materiality of signification (hence the call for a semiotic approach to technology), and, in a sense, a certain freedom to engage in intellectual experimentation (with no imposed canon). But ANT definitely partook in a general poststructuralist movement that was seeking alternatives to the intellectual machineries defended at that time by influential figures such as Louis Althusser, Jacques Lacan, and Claude Lévi-Strauss.

Constructivism in the Sociology of Science

The formation of ANT is, also in part, an episode in the history of science and technology studies, one mainly characterized by a materialist approach to agency and a constructivist understanding of truth (see Pickering, 1992, 1995). ANT is often presented as a reaction to (and a dialogue with) two threads in the understanding of scientific inquiry: the French tradition of the epistemology of science and the British tradition of the sociology of scientific knowledge. The idea that Nature does not speak for itself and that scientific facts are constructed is almost unanimously acknowledged in the French tradition in the epistemology of science exemplified by authors such as Alexandre Koyré, for whom scientific discovery is determined by structures of thought that are historically constituted. Whether grounded in an intellectual frame of reference or a rational method (in line with Gaston Bachelard or Karl Popper) or in the rules of a social institution or discursive habit (whether in Michel Foucault or Ludwig Wittgenstein's terms), these structures of scientific thought are definitely historically established. Thomas Kuhn's *tour de force* (subsuming all this under the notion of paradigm) bolstered and comforted this viewpoint. But what is ruled out from this perspective, ANT would claim, is the relevance of any empirical account of the concrete operations (experimenting, measuring, calculating, writing, communicating) that are needed in order to obtain scientific facts – precisely the type of inquiry envisaged by ANT. The intellectual movement that characterized the British tradition of the sociology of scientific knowledge was quite different, almost the opposite of ANT's direction of inquiry. Authors such as Barry Barnes and David Bloor (the 'Edinburgh School' in the sociology of scientific knowledge) or Harry Collins and Trevor Pinch (the 'Bath School') were working out a sociological response to a rather empiricist, inductive British tradition in the epistemology of science, quite different from the French tradition. Accordingly, their response emphasized the role of social interests and collective representations in the establishment of scientific truth and falsehood. Seen from this angle, ANT's emphasis on the study of scientific controversies (situations in which scientific truth and falsehood are still in the making) was appreciated, but its focus on the empirical operations of science and on the material conditions of scientific work appeared as a fatal step backward toward scientific realism and positivism. As exemplified in numerous debates (for exemplary studies, position statements and debates, see Knorr-Cetina and Mulkay, 1983; Bijker et al., 1987; Law, 1986; Pickering, 1992), ANT was trying to be constructivist and realist at the same time, by accepting that scientific truth and scientific reality do exist, but not without a painstakingly material process of instauration (Latour, 1987, 1999a).

The elaboration of ANT's constructivist realism found some hospitable terrain in other areas of science and technology studies. Harold Garfinkel's studies in ethnomethodology, as applied in particular to the understanding of laboratory work, shared to some extent with ANT an interest on the ongoing accomplishment of reality, be it social or otherwise. Studies in situated action and distributed cognition, as illustrated by the work of Lucy Suchman or Edwin Hutchins, developed an understanding of agency that was very much in line with ANT. Historians of science who, like Peter Galison, Lorraine Daston, and others, have highlighted the material cultures of scientific objectivity have contributed greatly to arguments that have been actively endorsed by ANT. The development of ANT from the 1980s onward trespassed, however, the perimeters of

science and technology studies. ANT or ANT-oriented perspectives are today present in a multiplicity of areas (organization studies, political science, anthropology, economic sociology, to name a few), although not always straightforwardly linked to issues of science and technology.

Central Problems

ANT has made explicit and attempted at treating a number of problems of social-scientific inquiry, sometimes creating adherence and sometimes sparking controversy. This has usually translated into the production and use of a number of recognizable concepts, precepts, standpoints, and representative case studies on the problem of agency, on the notion of translation and on the constitution of collective realities.

Generalized Agency and the Critique of Modern Reason

ANT is often associated in popular views with an insistence on 'nonhuman agency,' that is, on sources and agencies of action other than purely human, conscious, and intentional. In fact, ANT stands as a reaction to both the downplaying of human agency in accounts of events favored in the natural and formal sciences (an ellipsis of the action of the experimenter in a microbiology laboratory, for example, in reports of findings) and the downplaying of nonhuman agency in accounts of events favored in the social sciences and the humanities (an ellipsis of the actions of bacteria, the medium, and the laboratory instrument). The point is twofold. First, the events that need to be accounted for are the conjunction of all kinds of agencies, the variety of which cannot be subsumed under a simple human/nonhuman or intentional/unintentional divide. For example, in the microbiology laboratory, action is prompted by personal purposes, unconscious motives, physical bodies, social institutions, corporate actors, living organisms, technological devices, gravitational forces, atmospheric conditions, budgetary constraints, collective ideologies, measurement instruments, legal codes, etc. In short, as soon as something happens, there is action to be accounted for, and a good ANT account does not single out any particular form of action, be it social or otherwise. Second, the fact that accounts are usually biased in favor of one form or other of 'purified' agency, is due, ANT claims, to the legacy of modern reason, that is, to a style of thought that is most distinctively characterized by the instauration of a neat divide between nature and culture, or between the physical condition of the world and its political constitution. This is both a bias that needs to be overcome in order to account for the proliferation of hybrid realities that modernity itself prompted (hence the need to develop an appropriate vocabulary) and an object of anthropological inquiry as such, as posited in Bruno Latour's 'anthropology of modern reason' (Latour, 1993, 2013).

On the question of the nature of human agency alone, ANT is known for contributing to a double refutation: that of the modern, liberal ideal of the sovereign, emancipated individual and that of the equally modern, sociological ideal of the dominated, conditioned social agent. The idea of using actors' interests as ultimate explanatory factors was replaced, in early contributions, by the idea of studying processes of 'interessement' and elaborating how they come about (Callon and Law, 1982; Callon, 1986). The pivotal notion of 'attachment' and the notable case studies on drug addiction and music lovers that accompanied its development (Gomart and Hennion, 1999; Latour, 1999b; Hennion, 2005, 2007) allowed ANT to shift attention from the 'doing' to the 'making do,' and from the 'moving' to the 'being moved,' as a constitutive feature of humanity. Through such movement, ANT arrives at a rather anthropological and philosophical reconsideration of what a 'thing' is and of what it does (e.g., Latour, 2000, 2004a, 2007). On the vocabulary of agency in standard social theory, ANT reportedly pointed, from its inception, to the recurrent use of 'nonhuman' parlance in sociology when dealing with the agency of large actors such as 'society,' 'the economy,' 'the corporation,' 'the nation,' or 'the state,' actors whose agency is in part structured with the collaboration of social scientists (Callon and Latour, 1981). The purpose of ANT is not to deny such agency but, precisely, to describe how it is mounted.

Material Semiotics, Inscriptions, Translation, and Networks

The task of developing a 'convenient vocabulary' adapted to this view of generalized agency was a *mot d'ordre* in the early years of ANT (see Akrich and Latour, 1992). The crux of this vocabulary lay in a combination of two crucial ingredients: a semiotic treatment of agency (mainly based on Greimassian semiotics and the notion of 'actant') and a focus on material devices (inspired by the anthropology of technology and by the engineering of sociotechnical systems). The analysis of how a program of action or a script of conduct is inscribed or not into a material artifact, and of how it interacts with other programs or other scripts, stood as one key ingredient of the ANT recipe (Akrich, 1992; Latour, 1992). The semiotic, actantial analysis of scientific publications was accompanied by quite novel developments, at the time, that traced materially the networks formed by texts, for example, through coword analysis and bibliometric maps (Callon et al., 1986). Inventing new social-scientific literary styles altogether was also part of ANT's original endeavor (Latour, 1996).

ANT's particular blend of material semiotics is intrinsically pragmatist. Instead of considering reference or signification from the viewpoint of a binary partition between signs and things (or between mind and matter), ANT considers reference as a materially traceable operation of displacement, transportation, and circulation. As demonstrated by Latour in his minute examination of the scientific power of Louis Pasteur, the ability to refer to the anthrax bacillus within the laboratory setting; the ensuing ability to refer, in entirely new terms, to a disease affecting cattle; and the ability to transform an entire country altogether (its cattle, its farmers, its inhabitants, its bacteria, and its economy) can be traced back to the material organization of referential operations through which all these realities circulate (Latour, 1983; see also Latour, 1988). But this circulation does not happen without transformation, and the key notion here is 'translation.' The idea of translation is indeed the crucial vehicle for the material semiotic approach of ANT. It has been formulated in a number of writings, but Michel Callon's case study on the relationships between fishermen, scientists, and scallops in the Bay of Saint-Brieuc remains a classic (Callon, 1986). The idea of translation

operates as follows: the starting point, the empirical matter on which ANT operates, is best understood as a set of statements, which are embedded in a number of settings and which characterize a series of participating entities. Those statements (e.g., 'scallops do anchor,' 'fishermen want the bay restocked,' etc.) are deemed more or less problematic in the sense that they demand action to be taken, raise issues and concerns, or are prone to controversy. A translation, in ANT's sense, is an operation that transforms one particular problematic statement into the language of another particular statement: tackling problematic statement A in its own terms means in fact shifting terms and therefore tackling problematic statement B. This operation of translation transforms the issues at stake and the configuration of relations that link statements to one another. It also modifies acting capacities (since these statements are claims for conduct, and their strength is synonymous with power to act), and it engenders agency (since an operation of translation is both an empirical act and the condition of the configuration of a capable actor). This vocabulary resonates to some extent with an engineering-inspired problem-solving view, with some sort of a 'function' (in a mathematic sense) that would transform statements into other statements (early ANT formulations have indeed been criticized for this kind of tone, e.g., Star, 1991). But it also contains the theoretical potential of a nondualistic form of metaphysics: all that there is a network of ongoing operations of translation that define the agency of problematic statements. There is no need to revert to a distinction between an inside and an outside, or between actors and actions. The very notion of an 'actor–network' (a notion that spread through what was first labeled 'sociology of translation' but then became 'actor–network theory') conveys this intuition quite well: instead of considering a distinction between actors (that act) and networks (which actors form among themselves, in order, for example, to act collectively), the 'actor–network' is both the 'network-that-acts' and the 'actor-that-springs-from-a-network,' precisely what is constituted through processes of translation.

Constitution of Collective Worlds

Despite its praise for interdisciplinary and its distancing from a modern idea of 'the social' as displayed in standard social sciences, ANT portrays itself as some sort of a sociology (Latour, 2005). It does so in a quite particular sense: as a science of the formation and deformation of collective worlds, worlds that are constituted precisely through the material semiotic processes that ANT sets out to describe. This is 'sociological' not in the sense that it emphasizes 'social factors,' but rather in the sense that it generalizes a political understanding of the constitution of these worlds. ANT indeed is recognizable through the use of words imported from political science (e.g., 'spokesperson,' 'parliament,' 'association,' 'representative') in order to analyze, say, a laboratory and all its constituents. ANT can hence be seen as the generalization of a political frame to the understanding of all types of assemblages, not only human assemblies.

This strand of ANT is particularly important in contributions to political ecology and democratic theory (e.g., Latour, 2004b; Callon et al., 2009; Marres, 2012). These contributions claim that the ecological revolution in all its dimensions (generalization of environmental controversies, radical uncertainty on the externalities of innovation, unsustainability of the modern economic rationale, and proliferation of problematic entities) provide a blatant demonstration of the limitations of the standard social-scientific repertoire. Notions developed in ANT, such as 'hybrid forum' or 'parliament of things,' take into account both the democratic appraisal of issues of a technical nature – issues that provoke the emergence of new entities and new collectives – and the consideration of the constitution of nature as a political endeavor. Aspects of these ideas have had some impact in science and technology policy literature, especially through the topic of responsible innovation.

Insistence on the performative role that technical metrics, accounting methods, statistical techniques, management devices, marketing tools, or economic formulas (all vehicles for operations of translation) play in the constitution of the entities they refer to (the population, the firm, the economy, aggregate demand, profits and losses, capital, etc.) also partake of ANT's contribution to the understanding of the enactment of what standard social sciences call 'society' (Law, 1994, 2004; Power, 1996; Callon, 1998; Desrosières, 1998; Barry and Slater, 2005; Czarniawska and Hernes, 2005; Callon et al., 2007; MacKenzie et al., 2007). Investigations in the terrain of health care and biomedicine also illustrate the possible contributions of ANT to the understanding of the formation of bodily states and medical conditions and their relation to the formation of medical communities and patient organizations (Mol, 2002; Callon and Rabeharisoa, 2008; Keating and Cambrosio, 2003). Architecture and the built environment have also provided fertile ground for ANT explorations in the analysis of the construction of collective worlds (Farías and Bender, 2010; Yaneva, 2009). On these and other terrains, research inspired by ANT has contributed to novel orientations in the understanding of the formation of collective realities – or, in a sense, of society (at large).

Philosophical Developments

In the 1990s and 2000s, and in parallel to progress in a wide variety of empirical fields, proponents and commentators of ANT have engaged in a number of philosophical debates. In particular, ANT has reclaimed affiliation with the pragmatist tradition in philosophy, most notably with authors such as William James, John Dewey, Charles S. Peirce, and Alfred North Whitehead. The breadth of a nondualist approach to knowledge and of a materialist, semiotic approach to reality in pragmatism marks ANT's entanglement with this tradition. Rapprochement with the philosophical viewpoint of Gabriel Tarde obeys a similar logic, with an emphasis on contesting the dominant, modern understanding of society. Latour's philosophical elaborations also have played a pivotal role in the development of new approaches to metaphysics that focus attention on the reality and effectuation of objects (Harman, 2009; Latour et al., 2011).

Two versions of ANT, it can be said, are in circulation in the early first quarter of the current century. One, certainly more attached to the vocabulary developed in the 1980s and to the topics of inquiry that have most distinctively characterized the label 'ANT' through the years, works today as a widely used and acknowledged perspective in the social sciences, particularly

appropriate for the study of complex and controversial situations. Another one, rather experimental and philosophical in nature, shifts in a sense from exploitation to exploration, perhaps at the expenses of the neatness of the label 'ANT,' and engages with a number of serious issues of political philosophy. Perhaps the most crucial issue, which corresponds indeed to recent undertakings of Latour (2013), can be formulated as follows: how can a perspective that emerged as a frontal critique of the intellectual categories of modernity, including the political ones, consider ideals of political constitution (or political insurrection) that are nonetheless suitable for the maintenance and preservation, if not reparation, of a world largely inherited from modernity itself?

Adaptation, Fitness, and Evolution

Ward B Watt, Stanford University, Stanford, CA, USA

Abstract

'Adaptation,' a central concept in evolutionary biology, represents the degree of suitedness between organisms' characteristics and their environments. It is the cause of differences in organisms' performances of biological tasks that lead throughout their life cycles to reproductive success, the distinct concept of 'fitness.' Organisms' characteristics need not be adaptive but may be 'neutral' (i.e., they have no consequences for fitness or may be subject to various constraints). Misperceptions of adaptation may result from confusions of terminology. The assumption that all features of organisms are adaptive is common but misleading. Future study of adaptation will include diverse approaches and greater rigor of conceptual analysis.

Introduction

The adaptation, or adaptedness, of organisms to their environments is a central concept in evolutionary biology. It is both a striking phenomenon needing explanation and a basic feature of the mechanisms underlying the patterns of evolutionary stasis and change alike. The organism–environment interaction that the adaptation concept embodies is the causal driver of the process of evolution by natural selection. Its nature, role in the evolutionary concept structure, and limitations must all be understood if a clear view of evolution is to be possible. In particular, adaptations distinctness from and relation to the concept of fitness must be seen clearly. Only thus can evolution by natural selection be properly understood.

Adaptations Identity and Its Distinction from Fitness

If no concept is more central to evolution by natural selection than adaptation, then also none has been more debated. All the basic features of its definition are found in the work of Darwin, but progress in unfolding its full scope and implications continue even at present. Biological evolution, as distinct from cultural evolution (though often interwoven with it; e.g., Cavalli-Sforza and Feldman, 1981), is manifested as change in the genetic composition of populations over time (*see* Microevolution). Therefore, some genetic terminology is needed at the outset. A 'gene' is a functionally coherent sequence of bases in nucleic acid, usually DNA (except for some viruses), determining or influencing some biological structure and/or function. An 'allele' is one possible sequence (a variant) of a gene, determining one alternative state of gene action. Many organisms, including most animals, carry two copies of each gene (and are thus termed 'diploid'). 'Genotype' refers to the whole heritable composition of a creature, whether viewed gene by gene (e.g., carrying two copies of the same allele, hence a 'homozygote,' or one copy each of two different alleles, hence a 'heterozygote') or more broadly up to the whole 'genome' which includes all genes. 'Phenotype' refers to the expressed structure and function of the organism as it develops via interactions of its genotype with the environment in which development takes place (*see* Genotype and Phenotype). Present understanding of the complexities of the evolutionary process requires this terminology to avoid ambiguity and confusion.

Basic Definitions of Adaptation

As a general concept, adaptation or adaptedness is best defined as the extent of matching or suitedness between the heritable features (heritable functional phenotypes) of organisms and the environments in which they occur. In other words, adaptation comprises genotype–phenotype–environment interactions. It finds direct expression in the effectiveness with which organisms perform essential biological tasks (osmoregulation, locomotion, capturing food, evading predators, etc.) in their environments. As such, its states are in principle quantitatively measurable, or at least orderable, rather than only qualitatively organized. This general definition is found in many parts of Darwin's writing, as in the introduction to his *Origin of Species* (1859/1872) where a woodpecker appears equipped "with its feet, tail, beak, and tongue, so admirably adapted to catch insects under the bark of trees." Here, the phenotypic states of these morphological characters, modified as compared to simpler forms found in other birds, are related to their functional performance effects in acquiring food resources that other birds, lacking those specific adaptive phenotypic states, cannot reach.

Adaptation also refers to the process of successively descended, modified phenotypes becoming more suited, 'better adapted,' to environments via natural selection on variation in those phenotypes. Paleontology finds strong evidence for improvement of adaptation over time, as in the escalation of predator and prey attack and defense morphologies in marine invertebrates (Vermeij, 1987). Real-time studies have shown adaptive improvement directly, such as in the evolution of a bacterial stock in novel culture conditions over periods of 10^4 generations: a stock at an early stage in the process, if samples are frozen for later reactivation, is found to be inferior in performance to its better adapted descendants sampled late in the experimental history (Lenski and Travisano, 1994).

This evolutionary refinement of an adaptive state has led to debate over when a phenotypic feature may be called 'an' adaptation and when it may not be (i.e., how far it has been specifically selected for its current functional state). Given that

adaptive states differ quantitatively, any viable phenotype has some level of adaptation, and this debate loses urgency. Recognizing a phenotype as 'an' adaptation only if it is the best available at a given time (as argued by Reeve and Sherman, 1993) would require continuous revision as newer alternatives arise, and it offers no compensating advantage.

Elaborations of the Basic Concept

Gould and Vrba (1982) extended and refined definitions of adaptation in useful ways. In their terminology, 'aptation' describes the primary, historically unmodified relation of suitedness between phenotype and environment – that of any newly arisen variant, positive or negative, in its functional effects. They regarded 'adaptation' as the successive refinement of phenotypic suitedness by selection of newer variants, and coined the term 'exaptation' for the coopting of a phenotypic feature by selection for a new function, as in the modification of skull–jaw joint bones toward the ossicles of vertebrate ears (e.g., Romer, 1955). The exaptation–adaptation distinction poses problems of discrimination (how much change under a new selection pressure is needed before a phenotype of *ex*aptive origin is recognizable as presently *ad*aptive? See Reeve and Sherman, 1993) and also emphasizes that we are dealing with quantitative scales of variation, not alternate qualitative categories. Often the Gould–Vrba terms are not used unless the distinctions are pertinent to the issue at hand, and otherwise 'adaptation' is used as a generally inclusive term.

Another important extension of the adaptation concept is the work of Laland et al. (1996, 1999) on 'niche construction.' This term refers to the active modification of environments by organisms in ways favorable to their own function and fitness, as emphasized by Lewontin (1983). It occurs in diverse ways in different groups: for example, bacteria may release protease enzyme catalysts into their surroundings to aid in foraging upon potential food items, while among multicellular animals beaver lodges and dams are a dramatic case of such activities (aside from the obvious capabilities of humans in this direction). Evolutionary models incorporating niche-constructive feedbacks on organism–environment interactions may have very distinct properties from those not including such active forms of adaptation (Laland et al., 1996, 1999).

The Distinction between Adaptation and Fitness

Alternative states of adaptation are the causes of evolutionary changes through their differences in genotype–phenotype–environment interactions and hence performances of these phenotypes. These performances, minute by minute to year by year, cumulatively alter how long individuals live and how much they reproduce. In short, adaptive differences among phenotypes alter their demographic parameters: survivorship ($= l_x$ of demography, where x denotes time intervals) and male mating success or female fecundity ($= m_x$ of demography). These parameters are components of what, since the advent of mathematical population genetics, has been termed 'fitness' or 'Darwinian fitness' (though Darwin did not use the word in this way): the reproductive success of whole populations or of specific genotypes. Adaptation and fitness, then, are serially related concepts, but are in no sense the same.

In evolutionary genetics, fitness is usually measured as the net replacement rate of organisms, whether an average value for a whole population or more specific average values for particular genotypes. It is defined in 'absolute' terms as $R = \Sigma l_x m_x$ (e.g., Roughgarden, 1979) under simple demographic conditions of nonoverlapping generations and homogeneous reproductive periods (as, e.g., in annual plants or many insects). For complex demography in age-structured populations, the most similar expression is λ (the leading eigenvalue of the demographic 'Leslie matrix'), a number that summarizes complex interactions of age-specific survivorships and fecundities (e.g., Charlesworth, 1994; McGraw and Caswell, 1996). The *concept* of fitness is the same among these cases; what varies is the *measure* of fitness as is proper to each case. If either R or λ, as appropriate, is compared among genotypes by taking the ratio of each value to that of a chosen standard genotype, there result 'relative' genotypic fitnesses, whose value for the standard genotype is 1. Most evolutionary-genetic models use relative fitnesses for symbolic or numeric convenience.

Usage of the terms adaptation and fitness has changed dramatically since Darwin. He, Wallace, and other early evolutionists used 'fitness' as a synonym for 'adaptation,' and by 'survival' they often referred not to the demographers' life cycle variable l_x but to 'persistence over long time periods.' Spencers phrase 'survival of the fittest,' translated, meant 'the persistence through time of the best adapted.' Darwin had (necessarily) a clear view of the concept that evolutionary biologists now denote by the term 'Darwinian fitness,' but he represented it by versions of a stock phrase (for which he had no summary term), "the best chance of surviving and of procreating," in the *Origin of Species* (1859/1872). Failure to recognize these usage changes, and thus blurring of the sharp distinction between adaptation as cause and fitness as within-generation result, has led to much confusion in later literature, including mistaken claims of an alleged circularity of evolutionary reasoning.

The Roles of Adaptation and of Fitness in Darwin's Argument for Natural Selection

From the inceptions of both Darwin's and Wallace's ideas of natural selection, differences in adaptation among heritable variants played the central, causal role in the process (*see* Darwinism). Darwin formalized his argument in Chapter 4 of *Origin*, especially in its first paragraph and its concluding summary, in such a way that it can be cast as a verbal theorem – as Depew and Weber (1995) make clear by judicious editing of Darwin's summary. Here it may be reformulated in modern terms.

To begin the argument, there are three points 'given' by direct observation: (1) organisms vary in phenotype; (2) some of the variants are heritable; and (3) some of these heritable variants can perform their biological functions differently in a specific habitat (i.e., some are better adapted than others to that habitat). Then, Darwin's Postulate is that the better adapted, and hence better performing, variants in a habitat will survive and/or reproduce more effectively over their life cycles (i.e., have higher fitness) than other variants. Demography shows that greater reproduction of variants will maintain or

increase their frequencies in successive generations of a population. One thus concludes that when the Postulate holds, the best-adapted heritable phenotypes will persist and/or increase in frequency over time, realizing evolution by natural selection. This completes Darwin's Theorem.

The distinction between differences in organisms' adaptive performances, minute by minute to year by year, and resulting fitness differences among them over their life spans is simply the difference between cause and effect. Its recognition is essential to keep straight the logic of natural selection and to organize empirical studies of the process (Feder and Watt, 1992; Watt, 1994).

Alternatives to Adaptation in Evolution

Adaptation is not ubiquitous, and natural selection is not all-powerful. 'Darwin's Theorem,' as summarized in this article, is empirically testable and indeed may not hold in some well-defined circumstances. Two main sources of limitation on the scope of adaptation are now considered.

Neutrality

As Darwin wrote in Chapter 4 of *Origin*, "Variations neither useful nor injurious would not be affected by natural selection." The modern concept of neutrality (Kimura, 1983; Gillespie, 1991), which he thus described, is the null hypothesis for testing all causal evolutionary hypotheses. It occurs at each of the recursive stages of natural selection, as recognized by Feder and Watt (1992).

First, at the **genotype → phenotype** stage, genetic variants may differ in sequence but not in resulting function. For example, the 'degeneracy' of the genetic code often means that differences in DNA base sequence lead only to the same amino acid's insertion into a given position of a protein molecule. Alternatively, at least in the case of some positions in proteins, substitution for one amino acid residue by a similar one may sometimes have little effect on the protein's function.

Next, at the **phenotype → performance** stage, functional differences among variants may not lead to performance differences among them, as other phenotypic mechanisms constrain or suppress their potential effects. For example, in the physiological reaction pathway used by bacteria to digest milk sugar (lactose), a twofold range of natural genetic variation in a phenotypic parameter (the V_{max}/K_m ratio) is observed for each of the protein catalysts, or enzymes, catalyzing the first two reactions. When these variants' resulting performances were measured under steady-state growth conditions, variants of the first enzyme in the pathway showed sizable, reproducible differences, but no such effects were seen among variants of the second enzyme despite the similar size of their phenotypic differences – due to system constraints related to the position of the reactions in the pathway, analyzable by the theory of metabolic organization (Watt and Dean, 2000).

At the stage of **performance → fitness**, performance differences may not lead to corresponding fitness differences (e.g., if improved performance has less fitness impact above a threshold value of habitat conditions). For example, performance differences among feeding phenotypes (bill sizes and geometries) of Darwin's finches have little fitness impact when food is plentiful in wet seasons, but have much more impact when it is scarce in dry seasons (Grant, 1986).

Finally, at the stage of **fitness → genotype**, which completes the natural-selective recursion, small population size can allow random genetic drift to override fitness differences, as in the loss from small mouse populations of developmental ('t-system') mutant alleles that should be in frequency equilibrium between haploid gametic selection favoring them and recessive lethality at the diploid developing-phenotypic stage of the life cycle (Lewontin and Dunn, 1960). Because the usual statistical null hypothesis is that no treatment effect exists between groups compared, any adaptive hypothesis of difference between heritable phenotypes is *ipso facto* evaluated against neutrality by statistical testing.

Further, there is a subtler neutral hypothesis, that of association or 'hitchhiking': variants that seem to differ in fitness at a gene under study may be functionally neutral but genetically linked to an unobserved gene whose variants are the real targets of selection. But 'hitchhiking' predicts that fitness differences seen among variants will not follow from any functional differences among them, so it is rejected when prediction from function to fitness is accurate and successful.

Indeed, where substantive adaptive difference exists among genetic variants in natural populations, neutral null hypotheses may be rejected by testing at any of these levels, from phenotypic function to its predictable fitness consequences and the persistence or increase of the favored genotypes. This has been done, for example, for natural variants of an energy-processing enzyme in the 'sulfur' butterflies, *Colias* (Watt, 1992). The explicit test of adaptive hypotheses against neutral nulls gives important rigor to experimental study of natural selection in the wild (Endler, 1986).

Constraint

Gould (1980, 1989) emphasized that many features of organisms may not result from natural selection, but rather from various forms of constraint due to unbreakable geometric or physical properties of the universe at large or of the materials from which organisms are built, or other, more local biological limitations or conflicts of action. Functional or geometric constraints may play a major role in the form or function of organisms (e.g., in snail shells' form) (Gould, 1989), or in the negative interactions in combinations of individually positive amino acid changes, which constrain the paths of positive evolution of antibiotic resistance in bacteria (Weinreich et al., 2006).

Selection among phenotypic alternatives at one time may entail diverse predispositions or constraints at later times. In one such case, the tetrapodal nature of all land-dwelling vertebrate animals (the bipedality of birds, kangaroos, or hominid primates is secondary) follows from the historical constraint that their ancestors, lobe-finned fish, swam with two pairs of oarlike ventral fins having enough structural strength *ab initio* that they could be exaptively (i.e., not through natural selection) modified into early legs (e.g., Gould, 1980; Cowen, 1995). In a more pervasive case, the evolved rules of diploid, neo-Mendelian genetics constrain many evolutionary paths. For example, if a heterozygous genotype is the best adapted,

and hence most fit, in a population, it can rise to high frequency in that population but cannot become the only genotype present because it does not 'breed true.'

Conflicts among different aspects of natural selection may constrain the precision of adaptation in diverse ways. As a case in point, adjustment of insects' thermoregulatory phenotypes may be held short of maximal or 'optimal' matching to average conditions in cold, but highly variable, habitats, because such 'averagely optimized' phenotypes would overheat drastically in uncommon but recurrent warm conditions (Kingsolver and Watt, 1984). This illustrates the general point that environmental variance may sharply constrain adaptation to environmental means.

Misdefinitions of Adaptation or Misconceptions of Its Role

Many misdefinitions of adaptation err by confusing it with fitness in one fashion or another. Much of this may originate in the usage changes, discussed earlier in this article, between the early Darwinians and the rise of evolutionary genetics, such that 'fitness' ceased to be a synonym of adaptation and came to mean instead the 'best chance of surviving and of procreating' (e.g., Darwin, 1859/1872, p. 63). This entirely distinct concept is, as noted above, the cumulative demographic effect of adaptation. Some writers on evolutionary topics have been confused by inattention to these usage changes, but others have erred through conscious disregard or blurring of the adaptation–fitness distinction.

For example, Michod (1999), despite early recognition of the separate nature of adaptation and fitness and of their antecedent–consequent relationship (Bernstein et al., 1983), sought to collapse these concepts into different 'senses' of the single term 'fitness' to be used in different contexts to refer to both 'adaptive attributes' and their consequences in reproductive success. Authors may choose terminology for their own uses within some limits, but this usage is at best an ill-advised source of confusion, and at worst a mistaken conflation of distinct concepts.

Another misconception was asserted by Lewontin (1983) during an otherwise important argument for studying 'niche construction' (cf. above; Laland et al., 1996, 1999). Arguing that the adaptation concept implies 'passiveness' of adapting organisms, he criticized it for allegedly implying that adaptation is like 'filing a key to fit a preexisting lock.' But no such passivity is really in evidence. In Darwin's example above, the woodpecker's feeding 'strategy' actively transforms its environment compared to that experienced by more generally feeding birds, using a resource that those other birds do not even perceive. Further, Darwin's discussions (1859/1872, Chapter 4) of mutualisms between flowers and pollinators also show the constructive nature of those adaptations: pollinators obtain resource rewards from plants and spread their pollen during their foraging, and by supporting the reproduction of their food sources in this way, they increase their own future resource bases. Niche construction is thus *an important form of adaptation*, not distinct from or opposed to it.

Lewontin also misstated the role of adaptation in the evolutionary process, arguing that 'three propositions' – variation, heritability, and differential reproduction – alone were sufficient to explain natural selection, and that the adaptation concept was gratuitously introduced into the argument by Darwin for sociological reasons (e.g., Lewontin, 1984). This claim is wrong and has been widely critiqued (e.g., Hodge, 1987; Brandon, 1990; Watt, 1994; Depew and Weber, 1995). Adaptation is the one element that distinguishes natural selection from artificial selection or sexual selection. Without it, Lewontin's three propositions are sufficient only to define 'arbitrary' selection, wherein we do not know the cause of any differential reproduction of heritable variants. But the adaptive cause is, indeed, central to evolutionary change resulting from natural selection.

Finally, a serious barrier to effective study of adaptation has been a claim by Mayr (1961, 1980) that 'proximate causes' (phenotypic mechanisms) have little to do with 'ultimate causes' (evolution by natural selection) in biology. Since adaptation comprises genotype–phenotype–environment interactions as the driver of natural selection, this 'proximate–ultimate' dichotomy distorts the basic nature of the evolutionary process and discourages the breadth of approach needed for study of evolution (Watt, 2000, 2013; West-Eberhard, 2003; Laland et al., 2011).

Adaptationism and Its Drawbacks

Rose and Lauder (1996) identify adaptationism as "a style of research … in which all features of organisms are viewed a priori as optimal features produced by natural selection specifically for current function." Some, such as Parker and Maynard Smith (1990) or Reeve and Sherman (1993), hail the assumption of adaptiveness as a virtue, while others (e.g., Gould and Lewontin, 1979) indict it as a vice. The question is: is it helpful, or legitimate, to assume that adaptation is ubiquitous?

First, is it true that adaptiveness is often assumed in practice? The usual null hypothesis in statistical testing is that there is no 'treatment effect.' Thus, any statistical test of adaptive difference among character states assumes *ab initio* that there is *no* such difference (i.e., that the character states in question are *neutral*). Only if this null hypothesis can be rejected according to standard decision rules is an effect recognized. All the null models of population genetics itself, beginning with the single-gene Hardy–Weinberg distribution, start with neutral assumptions. Tests of the population genetic consequences of putatively adaptive differences in phenotypic mechanisms may or may not find departure from neutrality, but it is the routine 'starting point.'

Mayr (1988) argued for testing all possible adaptive causes for phenotypes before turning to the explanation of chance (i.e., neutral) origins. But this argument depends on a historicist approach to evolution. If one can analyze a phenotype by testing among neutrality, constraint, or adaptation with present-day experiments, historicism is not needed. Even fossil structures absent in living relatives may be studied functionally by various means (Hickman, 1988). A historical approach may sometimes be indispensable, but it is not the only one available to evolutionary biology.

As Gould (1980) observed, assuming the ubiquity of adaptation discourages attention to structural or constrained

alternative explanations of phenotypes. It is not enough merely to test one specifically adaptive hypothesis about some phenotype against neutrality; one should consider all feasible alternative hypotheses, including the constraint-based one that a phenotype does make a nonneutral difference to performance and thence fitness, but does so in a particular way because no other way is feasible or possible, rather than because it is 'optimized.'

Indeed, the strongest objection to adaptationism may be that using the optimal adaptedness of a phenotypic feature as a null hypothesis (as sometimes suggested by adherents of this view) runs the serious risk of falling victim to 'the perils of preconception.' How can a scientist making such an attempt know that the phenotypic function has been correctly identified, or that an appropriate adaptive hypothesis has been arrived at, to begin with (cf. Gordon, 1992)?

As a cautionary illustration, the behavior of certain 'laterally basking' butterflies in orienting their wings perpendicular to sunlight was at first guessed to be an adaptation to minimize casting of shadows, hence to avoid predators' attention. More careful study shows that it does not do so! Parallel orientation of the closed wings to the solar beam truly minimizes shadow. It was instead shown experimentally, with proper testing against neutral null hypotheses, that the perpendicular solar orientation is adaptive, but in relation to thermoregulatory absorption of sunlight (Watt, 1968).

Some users of adaptationist approaches do recognize these concerns, and they build optimizing models for testing in comparison to possible constraints or other alternative explanations (e.g., Houston and McNamara, 1999). Nonetheless, the intellectual hazards of assuming the adaptiveness of phenotypes outweigh the possible advantages. Certainly, studies of adaptive mechanisms in diverse organisms are routinely carried out, achieving results that are both rigorous and generalizable, without this assumption (e.g., Lauder, 1996; Watt and Dean, 2000).

The Future Study of Adaptation

Mechanistic studies of adaptation in the wild are increasing in diversity and effectiveness, as in the application of biomechanical approaches to the function of morphological adaptations (Lauder, 1996), or of molecular approaches to adaptation in metabolism and physiology (Watt and Dean, 2000). Diverse tools of modern 'genomics' and 'proteomics' may be used in the study of adaptation in complementary ways, either (1) focusing at first on natural variation in genes and processes of known function, and working upward through their genotype–phenotype–environment interactions to their performance and fitness effects in the wild (e.g., Wheat et al., 2006; Barrett and Hoekstra, 2011); or (2) screening organisms' genomes broadly for genetic variation that is associable with biogeographic or other patterns of possibly adaptive biological specialization (e.g., Fournier-Level et al., 2011; Hancock et al., 2011), then working downward to identify those genes and variants' roles in genotype–phenotype–environment interactions and their effects (e.g., Prasad et al., 2012).

At the same time, philosophical ground clearing may reduce misunderstanding or misapplication of the adaptation concept, and lead to better specific work as well as greater possibilities for general insight (Brandon, 1990; Lloyd, 1994; Watt, 2000). There has often been tension between the study of well-known 'model' systems, which can maximize experimental power, and the fascination with diversity that drives the study of evolution for many workers. Both have value for the study of adaptation, and the tension may be eased by the interplay of comparative and phylogenetic studies (Larson and Losos, 1996) with genetics-based experimental or manipulative study of organism–environment interactions and their demographic consequences in the wild. This synergism of diverse empirical and intellectual approaches holds great promise for the widening study of adaptation as a central feature of evolution by natural selection.

Abstract

Jane Addams (6 September 1860–21 May 1935) was a world-renowned social activist, public intellectual, political leader, author, and lecturer, and the first American woman (and second woman) to receive the Nobel Peace Prize. She was also a brilliant social thinker, at home in the humanities field of philosophy, and the social science fields of social psychology, sociology, anthropology, and political science. As the founder and leader of the first settlement house in the United States, Hull House in Chicago, she is considered to be a founder of the field of social work.

Biography

Born in Cedarville, Illinois, to a leading agricultural businessman and a woman admired for her charitable works, Jane Addams earned her B.A. degree from Rockford Female Seminary (later Rockford College), and aspired to earn an MD degree but abandoned that goal after an initial attempt. She spent much of her twenties ambitious to contribute to society but unsure what to do. She decided to found a settlement house after reading about the world's first settlement house, Toynbee Hall, in London. Following a visit there, she and a friend, Ellen Gates Starr, opened a settlement house in Chicago, Hull House, in September 1889.

Initially, Addams's intention was to offer clubs, classes, concerts, and sports to enrich the lives of her working class, mostly immigrant neighbors. However, they quickly educated her about the challenges they and their children faced due to low wages, dangerous working conditions, and long hours. As a result, while the settlement house remained committed to social and cultural enrichment, Addams's purposes expanded to include seeking ways to work with labor unions and women's organizations, some of them cross-class, to improve the working conditions of working people. Starting in 1893, when she lobbied a legislature for the first time, Addams became a strong advocate for worker rights, especially as they affected women and children. In 1903, she cofounded, along with other settlement leaders and labor organizers, the Women's Trade Union League. She was a member of the National Child Labor Committee and supporter of the 8-h day, the state women's pension laws (and later the federal law Aid to Dependent Children), and the minimum wage.

Eager for working women and women like herself to have the vote so that they could apply more effective political pressure on legislatures, Addams became a vice president of the National American Woman's Suffrage Association in 1911. She was among the nation's most prominent advocates for that reform, giving speeches to unions, clubs, college groups, and churches, and, in 1912, to voters, as part of her campaigning for Theodore Roosevelt as the presidential candidate for the Progressive Party.

Meanwhile, as the field of social work emerged in the 1890s, Addams found herself considered one of its early leaders, though she never referred to herself formally as a social worker. The field, consisting of prison workers, settlement workers (paid and unpaid), and charity workers (paid and unpaid), had disagreed in the 1890s and early twentieth century over the question of nature versus nurture (Addams siding with the 'nurture' position) but Addams's election in 1911 as the first woman president of the National Council of Charities and Correction (precursor to the National Council of Social Work) signaled that a majority of charity and social workers had come to agree that the environment played a critical role in 'causing' poverty.

Addams's path to peace advocacy began with her embrace, in her twenties, of Leo Tolstoy's ideas about Christianity, including his emphasis on the importance of nonresistance to evil. She had been interested in peace as early as 1893, when she became a member of the tiny Chicago Peace Society. Her central conviction, inspired by her interpretation of Tolstoy's Christian writings, was that antagonism of any sort, whether between individuals or nations, could never serve a constructive purpose. In 1898, when the United States engaged in the Spanish-American War, she realized that she would have to become either 'more or less a Tolstoyan' right away (Knight, 2005).

Addams eagerly read the thoughts of other influential authors on peace as well. In her second book, *Newer Ideals of Peace* (1907), she quoted L.T. Hobhouse's view that "universal and permanent peace" was not a vision but "an actual process of history." Both Addams and Hobhouse put their faith in the power of the growing social forces that in time could create the conditions of permanent peace. At the same time she agreed with British anti-imperialist economist John A. Hobson that this process could be derailed by the forces of economic imperialism (Addams, 1907).

She was soon a leader in the National Peace Congress, during a time when the men of high status were also active, but Addams's commitment, unlike theirs, did not change when World War I broke out. Elected in early 1915 as president of the Woman's Peace Party, she attended the International Congress of Women in the Netherlands and was elected president of the new organization formed there, the International Committee of Women for Permanent Peace, later renamed the Women's International League for Peace and Freedom (WILPF). She would remain its president until 1929.

During her presidency she built the organization into a forceful advocacy group for world disarmament, the spread of international law, and for pacifism. In the United States WILPF

and Addams were vilified for these supposedly dangerous views; from 1915 and continuing through the 1920s, she was mostly hated in her own country. The hate subsided somewhat when, in 1931, she was awarded the Nobel Peace Prize. Upon her death in 1935, she was freshly honored as the nation's leading citizen.

For much of the second half of the twentieth century few scholars recognized Addams as a significant intellectual. Indeed, when her ideas were considered she was assumed to hold the views typical of white, prosperous, reform women of her times regarding the inferiority of certain races, the superiority of the prosperous classes, and women's biologically dictated nature. Yet no one familiar with her body of work would make such a claim (Knight, 2005, 2010; Deegan, 2007).

Her Intellectual Development

The Early Years

As a child and young woman, Addams was fascinated with reformers and their ideas: Robert Owens's failed cooperative community, Lucy Stone's campaign for legal equality for women, and John Brown's impatience to see slavery end. She decided medicine offered the best way she could be helpful to poor people. The curriculum at the female seminary had little to offer her in the way of science but she and a friend, Ellen Gates Starr, founded a Science Club and she read Darwin's *On the Origin of the Species* and *The Descent of Man*.

After college, with more time to read, she read not only novels and history but also early works in social science that probed the nature of society and how it might be improved. Her reading list included Jean Baptiste Godin's *Social Solutions*, Ferdinand Tonnies's *Community and Society*, and Herbert Spencer's *Social Statics*. She also became an enthusiast for Auguste Comte's positivism in these years, particularly his idea of 'unity' – the belief that most people desired to feel a universal affection for other human beings.

Once at Hull House, Addams's interests came to include investigations. Already an admirer of Charles Booth's *Life and Labour of the People in London* (1889), she respected the power of statistics to capture the reality of conditions. The residents of Hull House, including Addams, soon became involved in various studies of problems facing their neighbors, including housing conditions, infant mortality rates, and the social value of saloons. Addams describes some of these in her two books about Hull House (Addams, 1910, 1930).

Hull House Maps and Papers

Most of these investigations were known only to Chicagoans, but in 1895, Hull House gained a national reputation for the publication of a book whose authors were officially listed as the 'Residents of Hull House.' The book's long title was *Hull-House Maps and Papers: A Presentation of Nationalities and Wages in a Congested District of Chicago, Together with Comments and Essays on Problems Growing Out of the Social Conditions* (Residents, 1895).

The book's significance has more often been assumed than assessed. For example, it is sometimes credited with setting new standards for social investigation. In fact the work on display was typical of the standards of the early 1890s, as a glance at the 1892 transactions of the American Social Science Association makes clear. And although *Maps* is sometimes described as having pioneered in its interest in women and children, only one of the 10 essays focuses on people in either category.

The maps in the book were a methodological breakthrough, but not an original concept since they were consciously modeled after Charles Booth's wage maps of London, including using the same color codes for wage levels. Deegan argues that the Hull House maps had a different purpose than those of adopted later by Chicago sociologists. The settlement maps were meant to be useful to the community, she claims, while the scholars' maps were for experts (Deegan, 1988).

Maps and Papers is often believed to reflect Addams's social thought, but it actually more reflects the thought of Florence Kelley, an experienced investigator who arrived at Hull House in 1892. The maps, the schedules, and two essays in the book all grew out of Kelley's work for the U.S. Department of Labor collecting Chicago data for its special report on wages, residential patterns, and nationalities of those living in the 'slums' of the nation's four largest cities (Deegan, 1988; Ross, 1998; Sklar, 1998).

The idea of publishing color-coded maps came first and then the residents decided to include expanded versions of five papers that some of them had presented at the Congress on Social Settlements, held at Hull House in conjunction with the 1893 Columbian Exhibition. The five papers included the two by Florence Kelley, on the sweating system and on wage-earning children. The other three were by Addams (on the settlement and the labor movement), Ellen Gates Starr (on art and labor), and Julia Lathrop (on county charity work). Rounding out the collection were five essays written by residents expressly for the book. These were on the maps project, the income and expenses of cloakmakers in Chicago, and three ethnic groups – the Jewish, the Bohemian, and the Italian communities – in Chicago.

Addams was proud of the book, the first with which she was associated, and disappointed when there was not a second printing, but she also did not want *Maps* to mislead the public regarding the main purposes of Hull House. In the Prefatory Note, she carefully stated that the energies of the Hull House residents "have been chiefly directed, not toward sociological investigation, but to constructive work" (Addams, 1895). She also noted that the maps and papers were based on "recorded observations [that were] … the result of long acquaintance" (Addams, 1895). She did not want anyone to think that the residents of Hull House saw their neighbors merely as objects of investigation from whom to extract data.

While *Maps* was not as pioneering as some have assumed, it was possibly more influential than earlier sociological studies because of its association with the famous Jane Addams, the famous Hull House and the important city of Chicago. Deegan (1988) argues that it launched the Chicago school of sociology, because of its use of mapping, its focus on some of the topics that Chicago sociologists would study for decades to come, and because it was about Chicago.

The book had a direct influence on another important study, W.E.B. DuBois's 1899 investigation, *The Philadelphia Negro*. DuBois's assistant for the project, who became an important contributor as well, was Isabel Eaton. She had been

a resident at Hull House. Addams recommended her to DuBois for the position, and Eaton was herself a contributor to *Maps*.

Jane Addams's Epistemology

Because Addams was first and foremost a reformer, her orientation toward knowledge was practical and placed a great value on experience. But she was also an intellectual. Compelled by the power of ideas to change the world, she spent a great deal of time in the company of other intellectuals, both socially and through reading. Thus she was both drawn to the academy and yet had a detached view of scholarly goals and methods.

In 1896 she published her first academic essay based on what she and others had learned from personal experience. 'A Belated Industry,' appearing in the first issue of the *American Journal of Sociology (AJS)*, was an expanded version of a speech on household labor she gave at the Chicago World's Fair of 1893 (Addams, 1896). She revised it again when making it a chapter of her first book, *Democracy and Social Ethics* (Addams, 1902).

Her second scholarly essay, "Trade Unions and Public Duty," was also based on experience. Published in 1899 in the *AJS*, it was a revised version of a paper she gave at the Congress of Social Settlements, combined with parts of a speech she gave about the 1894 Pullman Strike (Addams, 1899a).

In her third academic essay, Addams changed gears and wrote an original piece for a scholarly readership that tackled the question of the place of research in settlement houses and concluded that it did not belong there. Published in 1899 in the *Annals of Political and Social Sciences*, 'A Function of the Social Settlement' set forth Addams's view that the university's role was to generate and disseminate new knowledge, and the settlement house's role was to generate and improve it by experimentation (Addams, 1899b). (The interesting context for her argument is that in 1895 the University of Chicago proposed to make Hull House a part of the university, but Addams rejected the president's offer (Deegan, 1988).) But tucked behind this neat distinction is Addams's real and daring point: that knowledge is pointless unless the search for it is fully engaged with human experience from beginning to end.

Aware of the feathers she would ruffle with this essay, Addams sought protection by citing John Dewey and William James as agreeing with her, but that did not mean that either was her source for this idea. She had first encountered it in the writings of John Ruskin, Thomas Carlyle, and Matthew Arnold, and in the activist bent of the Social Christians (Knight, 2005).

In 'A Function of the Social Settlement,' Addams clearly distances herself (and the settlement house movement) from dry, abstract, specialized knowledge. The settlement, she wrote, "stands for application as opposed to research; for emotion as opposed to abstraction, for universal interest as opposed to specialization." Settlements were created "not with the object of finding clinical material, not to found 'sociological laboratories,' not, indeed, with the analytical motive at all, but rather … with a desire to use [the knowledge they possess] synthetically and directly, to test its validity and to discover the conditions under which this knowledge may be employed" (Addams, 1899b). Though she stated her position as representing the settlement movement, there were many, including her friend settlement house founder Robert Woods, who endorsed the concept of settlements as sociological laboratories (Lengermann and Niebrugge-Brantley, 2002). Addams was staking out her position in the debate.

Addams addressed scholars in person at the 1905 convocation at the University of Chicago in a speech titled, "Recent Immigration: A Field Neglected by the Scholar." Bearding the lion in its den, Addams charged that immigration scholars were relying on old views and traditions and therefore emphasizing false dangers from immigration – the destruction of the American way of life, etc. – rather than bringing their interpretations in line with the nation's 'present motley and cosmopolitan character.' Thus they were neglecting research's 'higher function': to resolve the contradictions between traditional beliefs and new realities. In seeing immigration as a threat, she wrote, "we are remaining constant to a truth we no longer wholly believe … and that is not justified by our latest information." (Addams, 1905).

This passage captures not only Addams's point that scholars tended to reflect the social consensus rather than challenge it, but also the passion she shared with scholars for the truth. At the same time, she was highlighting a problem that scholars rarely considered: the human tendency to resist changing one's mind. As she wrote in 1907, "[I]t is so easy to commit irreparable blunders because we fail to correct our theories by our changing experience" (Addams, 1907).

Addams also differed from most scholars in her method for discovering truth: she thought it could only be found in experience (a category that included observations and factual data but not abstract logical arguments). Addams's friend, George Mead, reviewing her book *Newer Ideals of Peace* in the *AJS* in 1907 caught this aspect of her epistemology when he astutely noted that she was arguing "not [for] the necessity of a deduction, but [for] the necessity of reality."

Addams cited Dewey and James to substantiate her pragmatism, but recent scholarship reveals that she worked out her version of a pragmatist philosophy earlier than either of the two famous male philosophers and that she was an important early influence on Dewey. In particular, in her thinking about democracy and about war, Addams was a pragmatist before Dewey, who did not reject moral absolutism completely until after World War I (Knight, 2005; Ross, 1998; Seigfried, 2011; Knight, 2014). Addams and James agreed on the need for a moral equivalent to war but it was Addams who turned this idea into a whole book, *Newer Ideals of Peace* (discussed below).

Addams believed interpretation based on experience was the essential method for arriving at the knowledge needed for effective reform. This involved both an ability to "interpret sympathetically the motives and ideals [of people whose] rules of conduct … [are] widely different from our own" (Addams, 1902) and an ability to revise one's own beliefs in response. She called that "the hard work of careful … self-examination." (Addams, 1910). Historian of science Dorothy Ross argues insightfully that Addams offered 'an interpretative form of social knowledge' and that it was 'relational in a double sense,' in that it was both based on her own experience in human relations and on her interest in the role of relational experience in understanding society (Ross, 1998).

Jane Addams and the Social Sciences

Jane Addams and Sociology

While Addams drew a bright line between the work of the settlement house and that of the university, she considered academics, particularly those in sociology, to be her professional colleagues. She was a founding member of the American Sociological Society (later the American Sociological Association) in 1905, and presented papers at its meetings. She was friends with most of the sociologists at Chicago, including Albion Small, George H. Mead, George Vincent, Charles Zeublin, Charles Henderson, and W.I. Thomas. In 1913, Small proposed that she take a half-time position in the department teaching graduate students, but she declined (Deegan, 1988). Just how compatible her ideas were with the men of the Chicago school is a separate question. Deegan emphasizes the collegial ties, and addresses ideas secondarily. Dorothy Ross highlights Addams's discomfort with their cautious devotion to the status quo (Ross, 1998).

Addams was influenced by and influenced the field. She had ties with W.E.B. DuBois, Richard T. Ely, Franklin Giddings, and Charles H. Cooley (Deegan, 1988); the syllabus for her 1898 University of Chicago extension course, 'Democracy and Social Ethics,' includes writings by scholar/friends Amos G. Warner, Sidney Webb, and Thorstein Veblen (Addams, 1898b). She was particularly interested in Veblen's notion of the instinct of workmanship (Addams, 1922). Her books were reviewed in the *American Journal of Sociology* and professors adopted her texts in courses (Deegan, 1988). But sociology at that time was pressing for increased scientific objectivity and knowledge for its own sake, which inevitably reduced Addams's influence, given her interest in knowledge's interpretation and application (in addition to the fact that she was female in a male field).

The sociologist whose ideas seemed closest to her own and whom she certainly influenced was Charles Cooley. He cited her work seven times in his 1909 text, *Social Organization*, where he argued for the central role of primary groups (family, friendship groups, etc.) as the source of one's ethics, a view that Addams had long held. Cooley's methods were also Addams's: case studies and empirical observation. Cooley also agreed that society was an experiment that led to enlarging the individual's social experience and to finding new ways to coordinate variety, points Addams first made in the 1890s (Deegan, 1988; Ross, 1998).

Addams wrote one sociology text for the classroom, *Newer Ideals of Peace* (1907). Her argument was that the old-fashioned ethic of militarism (which, drawing from Herbert Spencer, she defined as not just values related to war but the reliance on physical force as the solution to every difficulty and the embrace of hierarchal rankings in society) was too influential in current thinking about government and its roles, and was the cause of government's failures. Militarism should therefore be replaced by the new ethic of humanitarianism which would allow democratic governments to thrive. While her examples were mostly drawn from the United States, the book hints throughout that she had the world as much as her own nation in mind.

Beginning in the late twentieth century, and due to the important efforts of Mary Jo Deegan, Dorothy Ross, Patricia Madoo Lengermann, and Jill Niebrugge-Brantley to integrate early women sociologists into the history of the field, Addams began to receive recognition as an important sociologist, though her views remain controversial, as Ross, Lengermann, and Niebrugge-Brantley emphasize.

The field of social psychology was Addams's particular interest. Her library included the writings of Mary Follett, Normal Angell, and Graham Wallas. And her interest in social relations and the changing status of women are remarkably mirrored in the writings of Lester Frank Ward. John Dewey and William James were also leading social psychologists and both men viewed Addams's ideas with profound respect (Knight, 2010). In the early 1890s, well before James gave his lectures on the "varieties of religious experience," Addams wondered at the varieties of religious experience found in her immigrant, working class neighborhood, and pondered the role of emotions and experience in religious thought (Knight, 2005).

Jane Addams and Anthropology

While Addams's associations and intellectual connections with sociology are recognized, those with anthropology are not. Her intellectual interests were profoundly anthropological; she was a sociocultural anthropologist using methods of participant observation. Her neighborhood was home to immigrants of many different nationalities, many of whom came to Chicago as peasants. She sympathetically observed their encounters with modern, industrial, urban culture and wrote eloquently about their tensions with their children over dress, financial and social independence, and sexuality.

Although she used the terms 'primitive' and 'civilized,' she used them in ways that only careful scholarship can unpack. One of her most radical arguments was that those whom society called 'primitive' were actually the most civilized when it came to their sense of human brotherhood, and that they had much to teach those whom society called 'civilized' (i.e., Anglo-Saxons) (Knight, 2005). One of her most anthropological books was her study, *Spirit of Youth and City Streets* (1909), a sensitive exploration of the ways that youth, with their fundamental instincts for play, adventure, sex, and imagination, responded to the city.

She was also a close student of women and their ways of claiming power in a patriarchical society. Her essay, "A Modern Devil Baby," examined how an ancient fairy tale flamed to life in her neighborhood. Sheprobed how women wielded the rumor of the devil baby's presence at Hull House as a way to intimidate men into being better fathers. That essay was revised to become two chapters in *The Long Road of Woman's Memory* (Addams, 1916), an insightful study of how women's memories functioned to transmute the past, reinterpret the present, disturb conventions, integrate women with modern industrial life, and challenge war.

The works of anthropologists shaped her views on the distinctive place of women in early human history and her belief that the role of government should be based on the family's nurturing role. Otis Mason's *Woman's Share of Primitive Culture* (1894) supplied her with arguments for women as the founders of the family, which he called "parental government," and therefore for women being qualified to engage in modern government. In her unpublished 1911 speech, "The Woman and the State," Addams drew on Mason's and other anthropologists

ideas to argue that centuries of men's dominance in governance had created a situation harmful to human life (Addams, 1911; Knight, 2010).

So far Addams's ideas have apparently left no trace in anthropological scholarship though one groundbreaking anthropologist, Ashley Montagu, has called her "a genius," and her writings, "great literature" (Montagu, 1960). It remains for scholars to study Addams as a sociocultural anthropologist.

Jane Addams and Political Science

Addams was a moral philosopher whose core beliefs about human beings centrally shaped her understanding of how democratic politics worked and how it could potentially work. Her views about political democracy included ideas about citizenship, which she considered a responsibility shared by everyone in a democracy, and about the purposes of government, which she believed were to remove obstacles that prevented citizens from developing their full potential. Much of her work at Hull House and as a political activist was shaped by these convictions.

Her interest in morality in politics was partly compelled by the fact that Hull House was located in a ward represented by Chicago's most powerful and most corrupt alderman, John Powers. The neglect of the neighborhood's municipal services, particularly garbage removal, threatened the health of the ward. Addams took seriously the fact that Powers was popular with his voters and sought to understand it. Her resulting brilliant essay, "Ethical Survivals in Municipal Corruption," is a masterful interpretation of democracy in a mostly immigrant urban ward. Rather than condemn Powers for being immoral, she explored how the ethics of the voters found resonance in Powers' political strategies.

Addams's political actions as much as her writing on these subjects provide a window into her political thought. She was a political activist during the Progressive Era, lobbying in support of child labor, immigrant, and suffrage legislation. In 1889, she had felt political democracy was inaccessible to her as a woman but by 1912 she was fully engaged. In that year she seconded the presidential nomination of Theodore Roosevelt, campaigned for him, and became a leader herself of the Progressive Party. She served as a member of its executive committee for at least 4 years (Knight, 2010).

Although Addams wrote a great deal on the subject of democracy, political philosophers have only recently begun to study her ideas rigorously. This is challenging to do since she does not present her ideas systematically or concisely; important thoughts are strewn about her writings.

Political scientists have been drawn to study her book *Democracy and Social Ethics*, because the title includes the word 'democracy.' The book accurately captures her thinking as it evolved during her first 10 years at Hull House. It does not reflect her more mature understanding, gained from her expanding activities as a political activist. That is captured in her second book, *Newer Ideals of Peace* (1907). The title is misleading, since her subject is really the trend toward, and need for, more democratic government (see above discussion of the book).

Another excellent source for Addams's democratic thinking is a book she published 5 years before she died, *Second Twenty Years at Hull-House* (1930). Long out of print because the family controls the copyright, it is rarely cited but includes insightful chapters about social service and the progressive party, the woman suffrage movement, prohibition, and federal immigration policy.

Political scientists have recently probed Addams's ideas on many subjects. These include democratic citizenship, cosmopolitan citizenship, gendered and ungendered citizenship, and the ethic of care (Nackenoff, 2009; Sarvasy, 2009, 2010; Hanagan, 2013; Tronto, 1993). Though Addams is generally assumed to be a liberal, her ideas challenge many liberal assumptions. In particular, she rejected the individualistic ethic that undergirds liberalism (Knight, 2009).

Addams and Social Work

It is often said that Jane Addams was a founder of the field of social work. This is for several reasons. Settlement leaders, though not Addams, partly created the profession, founding one of the first schools of social work, as they were later called. (It should be noted that leaders of Charity Organization Societies (COS) had a greater influence over the emerging profession. COS leaders in the 1890s were devotees of a highly individualistic, classically liberal philosophy of human self-sufficiency that was diametrically opposed to the settlement house philosophy.) Also, Addams was the most famous and admired settlement house leader, making it natural to consider her a founder of the profession that attracted the interest of settlement movement enthusiasts.

Nonetheless, if founders should have a major influence in the fields they found, then it is difficult to see Addams as a founder. Perhaps the most salient disagreement between Addams and the new social work profession was her discomfort with the idea of professional training for settlement work. She saw herself and the residents as volunteers (being a resident at Hull House was never a paid position during Addams's lifetime, though it was at other settlements) who learned from experience while living in the neighborhood and being good neighbors. Furthermore, social work as a field came to be primarily associated with individual clinical work, which never appealed to Addams as a strategy for transforming lives or improving society. Addams was at core a reformer, a political activist, and she thought it a natural process that settlement volunteers would become engaged in social change around policy issues. This has generally not been the strength of the social work profession, especially once government funding became crucial to the field.

While Addams is credited as a founder of the social work profession and while scholars in the profession have written essays tracing her accomplishments and urging a return to her democratic ideals, Addams is too often viewed as a much beloved historical figure rather than what she also was – an intellectual and reformer with unorthodox ideas.

Conclusion

In the early twenty-first century, women intellectuals have begun to be acknowledged as contributors to the various social and behavioral sciences. It can therefore be hoped that

the past neglect of Addams's ideas in these various fields is coming to an end. The scholars in sociology and political science have led the way. And if, as it is sometimes thought, the social sciences in general are making a turn toward the qualitative, and away from the quantitative, Addams's methods and interest in how experiences and ideas shape human behavior should be of particular interest. Like her friends John Dewey and William James, Jane Addams had large and original ideas that will continue to reward scholarly investigation.

Addictions: General Considerations

Ulrich John, University Medicine Greifswald, Greifswald, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

A basic understanding of addiction is given. It includes addictive elements and disorders. Addictive elements are the addictive stimulus, behavior, conditions, and reward. Interactions of these elements may lead to addictive and further disorders. Addictive disorders include substance-related and non-substance-related disorders. Further disorders are related to addiction in that they depend on addiction elements but do not necessarily fulfill criteria for addictive disorders. Addiction has relevance for public health since highly prevalent risk behaviors such as tobacco smoking and overeating are involved. It is concluded that addiction is important in understanding and planning of interventions in public health.

Background

Importance

Addiction is a phenomenon that has been demonstrated in humans and animals. It may devastate social ties, behavior, and health. Starting from a historical perspective a basic understanding is presented for substance-related addictive disorders (SRD) and non-substance-related addictive disorders (NSRD). A public health perspective of addiction will be considered before conclusions are drawn.

Addiction at first glance seems to be a psychic phenomenon that increases and maintains 'bad behavior' despite known negative consequences. These include impaired social relations, health risk behaviors, as well as addictive and other chronic health disorders. There is international agreement that chronic disease largely depends on behavior (WHO, 2011). Behavior has been shown to be the single most influential among five domains that determine our health (McGinnis et al., 2002). Worldwide, among death cases, 10.5% have been attributed to tobacco smoking, 4.9% to overweight or obesity due to high caloric intake, and another 4.0% to unhealthy alcohol consumption (WHO, 2011). These behaviors compared to other factors are connected with the highest risk of global burden of disease (Lim et al., 2012). Smoking is one of the risk factors that are associated with the highest proportion of cardiovascular deaths, and smoking itself is related to the highest proportion of cancer death cases in the United States (Danaei et al., 2009). While tobacco smoking remained to be the single most preventable disease risk, there is an increasing overweight epidemic with a caloric intake that is too high and with a sedentary lifestyle (Finucane et al., 2011). Given this evidence, two questions arise: first, why do so many people adopt one or more of these health risk behaviors? Second, why do abundant smokers, alcohol consumers, and overeaters not change that behavior, although they may know about the negative consequence such as family or job loss, detriments on health, or premature death? One main part of answers to these questions is addiction. Addiction is a driving force in the adoption and maintenance of health risk behaviors.

History

Addiction is predominant in a number of terms that in large parts share the same meaning, from inebriety over addiction and dependence to addictive disorders (APA, 2013; Edwards, 2012). In 1964, the World Health Organization came up with the term dependence. In 1976, Edwards and Gross published the alcohol dependence syndrome (Edwards, 2012). It was a tremendous progress since it improved international standardization of diagnoses and provided a definition for research and clinical practice. The alcohol dependence syndrome helped to protect alcohol-dependent persons from moral disgust by the understanding of alcohol dependence as a disease. International classification systems of diseases, the Diagnostic and Statistical Manual of the American Psychiatric Association (DSM), and the International Classification of Diseases of the World Health Organization provided criteria and number of criteria required to diagnose alcohol dependence or abuse. The criteria were based on evidence and consensus of experts in the field.

In the most recent version of the DSM, DSM-5, new progress has been made by combining 'dependence' and 'abuse' into the category 'addictive disorders' that now includes SRD and NSRD. Addiction has been put more into focus in the frame of addictive disorders than was the case before (APA, 2013). The terms 'substance dependence' and 'abuse' have been dismissed. However, the criteria remained for SRD and have been adapted for one single NSRD in DSM-5, i.e., pathological gambling (APA, 2013).

What Is addiction?

Basic Understanding

Addiction is determined by social, behavioral, and physical factors. Addiction may be described by elements and disorders. There are four addiction elements: the external stimulus, the person's behavior, the conditions, and the reward. The elements are active in the formation and progress of disorders. Disorders include addictive and further disorders. Addictive disorders are SRD and NSRD. Further disorders, although not part of SRD or NSRD, are related to addictive elements (**Figure 1**).

Elements

Stimulus

A stimulus is a psychotropic drug or a nondrug stimulus. Psychotropic drugs include tobacco, alcohol, illicit drugs, and

Figure 1 Addiction: elements and disorders.

psychoactive prescription drugs. Psychotropic or psychoactive means that the substance acts on the central nervous system and has the potential to change mood, perception, cognition, or behavior. Clear evidence exists that only very few, approximately 100, out of about 30 million chemical substances, are known to be addictive in the sense that they are estimated as rewarding or pleasurable (Gardner, 2011). To alter mood, a substance requires to produce stimulation or sedation and antinociceptive or pronociceptive effects. Such effects, in co-occurrence with other specific elements, particularly specific conditions, may be experienced as feeling delighted or depressed. In DSM-5, a total of 10 classes of psychoactive drugs are addressed: alcohol; cannabis; hallucinogens; inhalants; opioids, sedatives or hypnotics, or anxiolytics; stimulants; tobacco; other substances; and caffeine. Caffeine differs from the other substances according to disorder groups. Non-substance-related stimuli among others may be games, goods, and the Internet.

Behavior

The following behaviors may be subsumed under the term 'addictive behaviors,' although there may be additional ones: intake of psychoactive drugs, eating food, using games with money, video games, Internet, buying goods, or sexual activities. These behaviors are needed for the development and maintenance of addiction.

A behavior that may become addictive such as gambling often is felt as pleasurable in early stages of practice, and as such the behavior is goal directed. Addictive behaviors develop over time. This process includes, among others, habit formation. Habits are largely automatized actions. Automaticity depends on the response of the individual and the context (Wood and Neal, 2007). Contexts may activate the performance of a response (Wood and Neal, 2007). Habits develop on grounds of associative learning (Wood and Neal, 2007). For the understanding of habits, one important question is how automatized processes develop a behavior that has originally been goal directed. In animal studies, drug use has been shown to increasingly become habitual and inflexible (Pierce and Vanderschuren, 2010). As part of this process, additional brain structures become involved (Pierce and Vanderschuren, 2010). However, addiction is a more complex phenomenon than habit formation. It needs supportive conditions.

Conditions

Conditions include social conditions and personality characteristics. Social conditions are factors at different societal or group level that may have an influence on using psychoactive substances or exerting addictive behaviors. At a societal level, ease of access to the stimulus and stimulus-related social norms are important factors. Stimuli such as cigarettes, alcoholic beverages, or gambling halls may be easily available but may also be restricted in access, as is the case by regulation in the framework of prevention. Social norms about drug use or addictive behaviors may influence the behavior of the individual, both at the social and individual level. The social network of a person may influence the behavior, particularly as long as a disorder has not yet developed. Peer groups may have a strong influence on whether a novice (e.g., in smoking tobacco or cannabis) will judge her or his first use experience as positive or negative. This may determine whether or not the stimulus will be accessed further on. In later stages of use trajectories, social marginalization may occur, as was documented in subpopulations of addicted alcohol consumers.

Personality characteristics include impulsiveness. Impulsiveness or impulse control disorders are one main underlying personality condition of addiction (von Ranson et al., 2013). Impulsiveness has been suggested by data to contribute to the risk of SRD, eating disorders, and gambling disorders (e.g., von Ranson et al., 2013; Karim and Chaudhri, 2012). Evidence suggests that an overlap exists between brain systems that are involved in SRD and brain systems that are involved in food intake (Dagher, 2009). One proposition maintains that palatable food may become addictive in the run of a binge pattern of consumption (Corwin and Grigson, 2009). In animal experiments, bingeing on food was associated with behavioral and neuronal changes that resemble those in drug addiction (Corwin and Grigson, 2009).

Reward

After having performed addictive behavior, reward may elicit the repetition of behavior. This addiction cycle is activated recurrently. The individual may perceive pleasant feelings or relief from unpleasant states, such as aches or agitation, as rewarding. A brain reward system has been shown by neurobiological research (Gardner, 2011). Specific brain areas are involved in self-administration of drugs. To this system belongs the nucleus accumbens and the dopaminergic system (Gardner, 2011).

Reward may be induced by craving for the stimulus and then performing the behavior. Craving has been understood as an urge to consume the psychoactive substance when being abstinent (Skinner and Aubin, 2010). This might also be true for non-substance-related stimuli. Craving may elicit

a motivation to consume the substance or exhibit the desired behavior. Craving is one of the diagnostic criteria of SRD according to DSM-5 (APA, 2013).

Reward and craving are the core underlying processes in one of the most common models of urge to smoke. It is assessed by the Fagerstrom Test for Nicotine Dependence (FTND: Heatherton et al., 1991). The FTND is based on the fact that nicotine is metabolized over time and that an urge to supply the body with nicotine takes place. The urge to smoke varies in strength among smokers. To assess the urge to smoke, question 1 of the FTND seems particularly useful: How many minutes after awaking in the morning pass before the first cigarette is smoked? Further questions follow this rationale.

Disorders

Two kinds of health disorders are related to addiction elements: addictive disorders and further health disorders. Both groups of disorders may include disturbance of social relations, behaviors, as well as mental and physical functioning. Addictive disorders are SRD and NSRD. Further health disorders are those that are affected by addiction elements, irrespective of whether an addictive disorder does or does not exist.

Addictive disorders

SRD and NSRD are apparent at the social, behavioral, and neurobiological levels. According to DSM-5, SRD include substance use disorders (SUD), substance intoxication, and substance withdrawal (APA, 2013). These three disorder groups are valid for the 10 classes of psychoactive drugs in DSM-5 except caffeine. For caffeine, there is intoxication and withdrawal, but no SUD.

SUD and substance withdrawal need chronic application of the substance in an amount that is suited to add to the development of disorder. However, the amount may differ by individuals. SUD is diagnosed using 11 criteria according to DSM-5 (APA, 2013). As part of these criteria, social, behavioral, and neurobiological levels of addictive disorders are represented by social impairment, risky use behavior, tolerance, withdrawal, and impaired control.

Social impairment includes recurrent use of the substance, which results in 'a failure to fulfill major role obligations at work, school, or home' (criterion 5); continued use of the substance 'despite having persistent or recurrent social or interpersonal problems caused or exacerbated by' effects of the substance (criterion 6); and important 'social, occupational, or recreational activities' being given up or reduced in the course of substance use (criterion 7, APA, 2013: p. 491).

Risky use behavior includes current use of the substance under circumstances that include hazards to physical health (criterion 8) and continued use of the substance, although the consumer knows of recurrent physical or psychological problems that may result from substance use (criterion 9, APA, 2013).

Tolerance is understood as a need for markedly increased amounts of the substance to achieve the desired effects or a diminished effect of the same amount of the substance (criterion 10). To withdrawal belong withdrawal symptoms and use of the substance to relieve or avoid withdrawal symptoms (criterion 11). There are eight withdrawal symptoms: autonomic hyperactivity as noticed by sweating or pulse rate above 100 beats per min, tremor, insomnia, nausea, transient hallucinations or illusions, psychomotor agitation, anxiety, and seizures. At least two of these must be met for withdrawal of the substance hours or days after cessation of using it (APA, 2013).

Impaired control includes the substance being taken in larger amounts or longer than intended (criterion 1), a 'persistent desire or unsuccessful efforts to cut down or control' substance use (criterion 2), much time having been spent in obtaining the substance (criterion 3), and craving 'or a strong desire or urge to use' the substance (criterion 4, APA, 2013: p. 491).

NSRD are also known as behavioral addictions or process addictions. According to DSM-5, a diagnosis of gambling disorder is provided if four or more of nine criteria are fulfilled. They include symptoms similar to SRD. Social impairment is indicated by having lost, e.g., social relationships or jobs because of gambling (APA, 2013). Risky use might be indicated by 'chasing' one's losses, i.e., after having lost money returning to gamble again (APA, 2013: p. 585). Impaired control may be seen in needs "to gamble with increasing amounts of money in order to achieve the desired excitement" (APA, 2013: p. 585). Internet gaming disorder is mentioned in DSM-5 as a condition for further study (APA, 2013). Other addictive disorders have been disregarded in DSM-5 because of insufficient evidence.

SRD and NSRD share common features of addictive disorders. The individual accesses the addictive stimulus repeatedly with goal-directed and habitual addictive behaviors. One effect of this is that some temporary satiation occurs before the individual restarts to engage in the behavior. Attention of the individual is increasingly absorbed by the addictive stimulus. Other obligations or interests are neglected more and more in favor of being concerned about the addictive stimulus. Social relationships and mental and physical functioning may become disordered. Control over the stimulus decreases (Sussman and Sussman, 2011).

In detail, SRD and NSRD share 13 common features. Among them, nine are core phenomena of addiction, three are related to the development of addiction, and one is related to treatment. The nine core phenomena are, first, a "failure to resist an impulse, drive, or temptation to perform an act that is harmful to the person or to others" (Grant et al., 2010; APA, 2000: p. 663). Second, for part of the behavioral addictions, the individual "feels an increasing sense of tension or arousal before committing the act and then experiences pleasure, gratification, or relief at the time of committing the act" (APA, 2000: p. 663, Grant et al., 2010). Third, SRD and NSRD seem to have common cognitive (Grant et al., 2010) and, fourth, learning and memory processes involved (Karim and Chaudhri, 2012). Fifth, individuals with SRD and those with NSRD show high impulsiveness (Grant et al., 2010). Sixth, SRD and NSRD seem to share common neurobiological processes such as alterations of dopaminergic pathways (Grant et al., 2010; Karim and Chaudhri, 2012; Ashley and Boehlke, 2012). Seventh, genetic evidence supports that NSRD may share genetic grounds with SRD (Grant et al., 2010). Eighth, there is comorbidity between pathological gambling and SRD (Grant et al., 2010). SRD and NSRD are both comorbid to further mental disorders. Ninth, there seems to be evidence that SRD and NSRD become obvious after shorter time among females than among males (Grant et al., 2010).

Development of both SRD and NSRD includes a decrease in positive mood during repeated behavior or a need to increase behavior intensity (Grant et al., 2010). Second, increasing focusing on, and engagement in, the addictive behavior interferes with other life domains such as role obligations or interests (Grant et al., 2010). Third, trajectories of addictive disorders over the life course seem to be similar among SRD and NSRD, with a beginning at age below 20 in many cases. Furthermore, treatment use is similar among individuals as SRD and NSRD are often treated in a similar way.

Further health disorders

Detriments of health other than addictive disorders belong to addiction irrespective of whether an addictive disorder does exist or not. Further health disorders are related to addiction in that they depend on addiction elements. It may be the case that all four elements of addiction are present in a disorder that has not been subsumed under the category 'addictive disorders.' Obesity from eating more food than is needed by the body may be such a further health disorder. In addition to overeating, relevant behaviors are particularly tobacco smoking, alcohol risk drinking, and sedentary lifestyle. There is clear evidence of co-occurrence of addictive disorders with other disorders of mental and physical health. A variety of psychiatric or physical disorders such as depression or obesity may precede, accompany, or follow an addictive disorder. Main aspects of further disorders following from substance use are the amount of intake and the time since quitting substance use. Evidence suggests that underlying common causal processes might add to such disorders. Addiction elements in part may explain why people maintain behaviors that are known to be health detrimental.

Taken together, addiction includes public-health-relevant elements. Each of them alone and interactions among them may add to the development of such disorders. This understanding is more comprehensive than models according to which addiction itself is disease (American Society of Addiction Medicine, 2013).

Addiction Severity

Addiction severity is important for the understanding of causal relations between addiction elements and SRD, NSRD, or further disorders. In DSM-5, mild SRD except caffeine requires two to three; moderate, four to five; and severe, six or more of the 11 criteria (APA, 2013). In an alternative approach to assess addiction severity, self-statements of symptom frequency are used (John et al., 2003).

Addiction severity may further be assumed from the strength of the single addictive elements and interactions among them. Stimuli might vary in their intensity and differ according to their reinforcing properties. This indicates the addictive power of a stimulus. It might be determined on grounds of relapse, strength of craving, or efforts to access the stimulus. Individuals might differ in vulnerability to these criteria of addictive power. Behavior may differ according to characteristics such as repetitiveness. According to health disorder, one main behavior characteristic is dose, e.g., number of cigarettes smoked per day. Conditions might more or less support the fact that addiction and reward differ in strength of effects on individuals.

Public Health

Relevance of addiction for public health is given by the prevalence of disorders and by approaches to improve public health. Prevalence data are differentiated according to whether the disorder was currently present, i.e., during the last 12 months prior to data collection, or lifetime, i.e., at any time during life. Data that have been collected before DSM-5 were published. In several studies, DSM criteria for dependence or abuse were used, which in the majority are comparable with DSM-5. For the United States, results of three nationally representative surveys among adults are available: the National Comorbidity Survey Replication (NCS-R) (Kessler et al., 2004), the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) (Grant et al., 2004), and the National Survey on Drug Use and Health (Samhsa, 2011). NCS-R data revealed 1.3% current and 5.4% lifetime prevalence for alcohol dependence (Merikangas and McClair, 2012). Alcohol abuse or dependence was found for 8.5% among the general population currently and for 30.3% lifetime in NESARC, and for 4.4% currently and 18.6% lifetime in NCS-R. Drug abuse or dependence prevalence was 2.0% currently and 10.3% lifetime according to NESARC, and 1.8% currently and 10.9% lifetime according to NCS-R (Merikangas and McClair, 2012). The data collection differed in that the NCS-R used the Composite International Diagnostic Interview (CIDI) and the NESARC used the Alcohol Use Disorder and Associated Disabilities Interview Schedule. Also, criteria for SUD diagnosis differed (Merikangas and McClair, 2012). This difference is likely to be a reason for the different in prevalence estimates. Both interviews provide DSM, version IV, diagnoses. Prevalence estimates for residents aged 15 or older in the European Union countries revealed that current alcohol, opioid, and cannabis dependence were among the four most prevalent mental disorders (Wittchen et al., 2011). The CIDI methodology was used in a study for 17 countries from Africa, America, Asia, Europe, and New Zealand. The samples included 85 052 respondents for the face-to-face interview. Findings show lifetime prevalence rates for SUD from 1.3 to 15.0% (Kessler et al., 2007).

The data revealed differences according to gender and age of onset of alcohol consumption. The prevalence rates for current SUD (alcohol or illicit drugs) among males were found to be nearly double (11.9%) that among females (6.1%) in the US National Survey on Drug Use and Health (Merikangas and McClair, 2012). It included a general population sample of residents aged 12 or older. Among them, 8.7% had an SUD. Among those aged 21 or older, the subpopulation that had drunk alcohol at age 14 or less were more than 5 times as likely to have alcohol dependence or abuse compared to those who had their first alcohol consumed at age 21 or more(Samhsa, 2011). SUD are related to a variety of social factors including low education (Schulden et al., 2009).

Eleven addictive disorders, SRD and NSRD including eating disorders, have been considered for one prevalence estimate. According to it, 47% of the US adult population may have signs of addictive disorders (Sussman and Sussman, 2011). As part of this, overweight is a main problem from a public health perspective. Prevalence of overweight increased worldwide (Finucane et al., 2011). Eating disorders such as anorexia nervosa or bulimia have lower prevalence rates. Epidemiologic

research showed consistently high psychiatric comorbidity of SRD and NSRD, particularly with mood, anxiety, and personality disorders (Schulden et al., 2009).

Addiction informs approaches to improve public health. It seems self-evident that preventive efforts should be helpful in extending life expectancy and in reducing disability and low quality of life. Considerable success of public health approaches such as governmental action to control for the risk behavior was demonstrated (Lightwood and Glantz, 2013). Comprehensive programs that include a variety of single preventive measures are most likely to be successful. The single provisions in such programs seem to add to effects at the national level (Lightwood and Glantz, 2013).

One main restriction in preventive action using a comprehensive approach of action is that too few countries so far have spent considerable effort on it. In many countries, there are strong barriers against the implementation of preventive measures that have been proven in practice. However, there are also limitations of our knowledge. We do not know enough about how addictive disorders or further disorders act as barriers against change of addictive behavior. Specific intervention approaches that are most effective in a public health perspective are not sufficiently known yet. A promising preventive strategy is the implementation of specific measures, particularly tax increases, as demonstrated in case of smoking reduction (Lightwood and Glantz, 2013). Curbing tobacco smoking and eating disorders are of high priority.

Conclusion

Evidence from social, behavioral, and neurobiological fields clearly reveals that addiction exists. People exert risk behaviors against barriers and without being forced directly by anyone. Addiction may be characterized by elements and disorders that are interrelated at social and behavioral levels. Social, behavioral, and further aspects have been included in classification systems of diseases. Addiction is a useful element in understanding how to curb the health risks of psychoactive substance use and NSRD.

Some caution is needed when SRD and NSRD are considered. First, there is a risk of 'pathologization' since the threshold of labeling somebody as suffering from 'mild addictive disorder' is critically low. Second, 'addiction' as a term is often used in everyday life for a variety of repetitive and rewarding behaviors. It is a task to transfer knowledge about more restrictive criteria from science to the general population. Third, NSRD may not always be easily detected and defined. In spite of this, addiction is important to be considered in public health, particularly by addiction-related further health disorders, in addition to addictive disorders.

Administration in Organizations

Abstract

Administration in organizations emerged as a specific field of inquiry for social sciences in the middle of the twentieth century. Herbert Simon has defined a program that allows social sciences to move from principles to concepts about action and action taking. Four main perspectives of administration and management are currently influential for further knowledge building as well as for practice-oriented approaches: the art and craft of handling strategic actors and power-based processes, the processes by which moral communities are built and integrated, the cognitive and epistemic dynamics generating cohesion and shared identities inside differentiated organizations, and domination regimes.

Administration in organizations – sometimes referred to as administrative science, or management theory – is a mid-twentieth-century knowledge construct that is considered a scientific revolution. Social sciences such as sociology and political science consider management issues and practices to be a specific field of inquiry that should not be left, as before, to the sole attention of microeconomics or mechanical engineering-inspired principles. It deals with action and action taking in social units that follow some particular purpose: public agencies, firms, and voluntary associations (*see* Bureaucracy and Bureaucratization). How far is it possible within such apparently rational entities to mobilize heterogeneous resources and differentiated logics of action so as to mobilize people and behaviors around similar agendas, and to integrate them so as to induce compatibility and cooperation between them, from top to down, from upstream to downstream, and across hierarchical levels and the inner division of labor?

Generating efficiency in achieving common goals and policies, a recurrent issue in profit-oriented, not-for-profit, and public administration, is explored by theories and based on empirical observations that explain behaviors and outcomes and even make them more predictable. Four approaches derived from social science inquiry shall be presented that play an influential role, whether for current knowledge building or for educational and professional purposes: the organization as an arena for strategic behavior, administration as moral community building, the organization as a cognitive and knowledge set, and administration as the agent of societal dynamics.

From Principles to Concepts

Modern management and organization thinking are rooted in the industrial revolution. What is often called the classical theory was dominant well into the 1940s.

The extensive use of machines and its corollary, specialization, meet competitive requirements to mass-produce low-cost standard products supplied by poorly skilled labor forces. In this setting, a human organization is assumed not to be different from a machine: what basically matters is its formal design. Basic assumptions are that factories exist to accomplish economic goals in accordance with rational criteria of choice, and that there always exists one best way, and only one, to solve a problem. Administration is supposed to be a matter of science. Action guidelines can be derived from universally applicable principles, whatever the type of organization is: centralization of equipment in factories, hyperspecialization of tasks, unity of command, and salaries based on individual financial incentives.

Mechanical engineers are in charge of designing the division of labor and defining the right procedures. They govern by principle because they are knowledgeable. Daily administration relies on two principles. What is expected from the workforce is basically conformity and discipline: foremen are hired to ensure that procedures get enforced. And workers, while considered ignorant and therefore not entitled to suggest alternative administrative approaches, are assumed to be basically motivated by greed: bonuses drive their behaviors to deliver productivity.

Some of the leading theorists are well known, such as Taylor (1911), an American manufacturer; Elton Mayo, a psychology professor at Harvard University; and Fayol (1949), a French engineer. While Fayol was handling the issues of how to manage a firm as a whole, Taylor was defining expertize about how to get the individual worker organized, and Mayo was exploring how closely actual individual behaviors matched the assumptions made by the classical school.

A strong attack was launched after World War II challenging such oversimplistic, mechanistic views of administration, in particular, by scholars trained in sociology and in political science. Simon (1946) emerged as the most prominent rebel.

According to Simon, principles as defined by the classical school are merely proverbs: they are neither true nor false. Simon criticizes in a rather abrupt manner the relevance of such an approach. Rigid task specialization, span of control, and unity of command lead to impasses. They are conflicting and inconsistent with most situations that administration faces. With equal logic, they are applicable in diametrically opposed ways to the same sets of circumstances, as suggested by empirical observation. Therefore, in order to become a really scientific theory, administration in organizations has to substitute concepts for principles and make them operational.

In a subsequent book, Simon (1947) lays the groundwork for administration as a specific field of inquiry. He sketches a conceptual framework, the meaning of which corresponds

to facts or situations that are empirically observable. He questions, for instance, the relevance of the principle of absolute rationality. In organizations, even if they are purposive, individuals do not have the intellectual or informational capacity to maximize, and they are also vulnerable to their surrounding social and emotional contexts. What human beings do when making decisions is to satisfice: they try to find trade-offs between preferences and processes, and they do the best they can where they are. Human and organizational decisions are, therefore, subject to bounded rationalities.

In addition, efficiency is not a goal that is shared the same way by everyone in the organization, including the managers, nor can it be defined *ex ante*. It should be a research question, starting from the hypothesis that the individuals or the organizations themselves carry a specific definition of what is good or correct from an efficiency point of view. In more general terms, contexts vary, and they make a difference. Organizations are local orders with specific characteristics.

Simon extends Max Weber's perspectives: administration belongs to the domain of rational action. Firms or public agencies are organizations driven by purposes. But managers rely upon the mediation of an organized setting in order to implement goals, purposes, or values. Therefore, the organization simultaneously provides a resource and becomes a constraint; managers experience it as a solution as well as a problem. Simon underlines the necessity for social sciences to approach administration as a field aimed at understanding the nature of empirical phenomena. Its primary goal is not to formulate solutions for action but to consider action as a problem under scrutiny. Practitioners could nevertheless rely upon relevant findings and apply such a body of knowledge – or part of it – to enlighten problem solving. Such an agenda is structured around studying the actual functioning of organizations.

In a more specific way, Simon defines decision-making processes or action as the core concern of a scientific discipline of management. Any decision or action can be studied as a conclusion derived from a set of premises by the organization or an individual. Some premises are factually grounded: they link a cause to an effect. Therefore, they are subject to testing in real life. Other premises are of a different nature: they are value grounded, made out of norms or ethical references. In this case, they are not empirically checkable. While both categories are not separable in action, analysts have to separate them and focus upon factual premises only.

Firms and public agencies should also be treated as open organizations. They do not and cannot exist as self-contained islands within society and the market; they are linked to specific environments. The relationships structured between the inside and the outside play very important functions. Where and how an organization is embedded, and what is exchanged, are phenomena that have an impact on an organization's inner functioning as well as on the environment.

Philip Selznick describes how an American federal authority gains support for its programs within local communities where it operates (Selznick, 1949). The concept of cooptation refers to a social process by which an organization brings outside local milieux and their leaders into its policy-making process, enabling such elements to become allies rather than a threat to its existence and its mission. Bringing the environment back in solves a major problem that classical approaches of public administration did not address especially when dealing with public administration. Two of his founders, Woodrow Wilson and Frank J. Goodrow, had been calling for a theory of public administration that made a dichotomy between politics and administration, between the elaboration of the policy by policy makers and the execution of that will by bureaucratic enforcement agencies. Selznick suggests that such a postulate should become a research question. He also proposes that, beside organizational phenomena as such, science should consider institutionalization dynamics, which means how values and norms are diffused and appropriated, and what impacts they have on managerial action taking.

Managing Arenas for Strategic Behavior

Simon's agenda paved the way for a behavioral revolution in the field of administration. During the 1950s, at the Carnegie Institute of Technology and under his leadership, he reviewed with James March studies of bureaucracies authored by social scientists such as Robert K. Merton, Philip Selznick, and Alvin W. Gouldner. They compared various models of bureaucratic behavior (March et al., 1958). In highly proceduralized organizations, whether private or public, individuals, and groups do not remain passive: they reinterpret rules and procedures, they play with and around them, and they use them for secondary purposes of their own such as increasing their autonomy inside the hierarchical line of authority or bargaining their participation with the organization. At an organizational level, administration by rule generates dysfunctional processes. Formalization and centralization induce vicious circles. In order to fight the unintended consequences that such tools generate – such as rigidity or inner-silo effects – organizations administer themselves by using more rules and by increasing centralization, therefore reinforcing rigidity and inner differentiation.

The Carnegie School also criticizes the theory of the firm as defined by orthodox microeconomics. Organizational decision making is the focal point. Is utility maximization the main function that business firms do, in fact, achieve? Cyert and March (1963) study how trade-offs are structured and activated inside a company, at their top as well as middle levels, around action taking and choice processes. Negotiations occur through which coalitions impose their demands on the organizational objective. It is most likely that any organization functions like a polyarchy: single members do not share an identical definition of its mission, goals, and collective interest. Simon's conception is demonstrated as being applicable to economic actors: satisficing is a much more powerful concept to explain their strategic decisions than maximizing economic profit. Such is specifically the case of pricing in an oligopolistic market. In other words, organizational structure and inner political games determine rational behavior.

Conflict is a basic attribute of any organization. Business firms and public agencies are not monolithic entities or integrated machines sharing one common purpose. They behave as pluralistic systems in which differentiated and even antagonistic interests float around, conflict, define acceptable compromises, or induce temporary cooperation. They look like political coalitions between subgroups (March, 1962). From an

action-taking or administrative perspective, organizations require their leaders to develop skills that are less analytical than behavioral. Administrators are close to political brokers, and negotiating and bargaining inside their organizations are crucial tasks to handle. A firm looks like an arena for strategic microbehaviors, a collection of subunits pursuing separate goals. The role of administration is to structure inducements so that each individual subunit identifies its interests with those of the firm and, thereby, contributes to its mission. Executives at the top behave and decide accordingly to roles that are more or less social rites (Mintzberg, 1973).

In the 1960s, the behavioral approach widened internationally and gave birth to a stream of organizational researches about decision making, power, and efficiency.

Allison (1971) studied the same event – the US presidential handling of the 1962 Cuban missile crisis – comparing three different paradigms about decision making. An organizational process model, which is clearly derived from the Carnegie School approach, completed with a political process model, which deals with partisan politics and presidential tactics on the public opinion scene, shows a superior ability compared to a rational actor or classical model to explain how President John F. Kennedy addressed the challenge and which outcomes were elaborated, despite the game theory–based techniques used by the Executive Branch to define rational solutions. Lindblom (1959) too takes a hard look at the rational model of choice. He rejects the notion that most decisions should be made based on total information processes. He suggests that synoptic approaches provide self-defeating strategies for action. Instead, he defines the whole policy-making processes as being dependent upon small instrumental decisions that tend to be made in a disjointed order or sequence in response to short-term political conditions. Such a muddling-through view prescribes managers to make small changes at a time and at the margin, not focusing too much or explicitly about content, and whenever it is possible and if needed making some minor concession – two steps forward and one step backward.

Do formal decision makers in certain contexts really play a relevant part in how decisions are made? A so-called garbage can model of choice suggests that it might well not be the case at all, in particular in organizations that are either highly bureaucratic or, at the opposite, very loosely structured (Cohen et al., 1972). Choices are characterized by ambiguity about goals, intentions, technologies, causation, participation, and relevance. What looks like a problem to actor A looks like a solution to actor B. Formal opportunities for choice look after problems to handle. Decisions are made without being considered by the participants as being made. Such anarchic contexts occur in specific organizational settings such as bureaucracies and very loosely formalized structures such as universities. Nobody is really in control of the process, and decisions are experienced as random-based outcomes. The implications of such a model for top managers are that they should not use quantitative tools as instruments of government or intervene in tactical ways but keep their hands free for what they consider fundamental issues and use two basic vehicles as action tools: the selection of their immediate subordinates and a redesign of their organization's formal structures.

Power phenomena are viewed as key variables for understanding and administering. The French sociologist Crozier (1963) offers a perspective that helps interrelating microprocesses (behaviors of single actors) and macroprocesses (the functioning of the whole organization). Individuals and groups are pursuing rational strategies: they try to fulfill goals and satisfy vested interests that are structured by the specific context within which their act takes place. Asymmetric interdependence relationships link them together: some are more dependent than others to satisfice their stake or goal from the discretion of others rather than from their own goodwill. Those who control a source of uncertainty on which others depend control power bases and are able, in exchange for their goodwill, to set up the rules of the game. In other terms, organizational functioning and change derive from the social regulation processes as induced by the actors who, at various levels of the pyramid, try to make their specific and heterogeneous strategies or logics of action compatible. From a managerial point of view, such a comprehensive framework implies that administration is about the art and skills to reallocate uncertainties and power inside the organization and, therefore, to structure interests inducing the actors to cooperate or not. Bower (1970) applies such a perspective to strategic investment planning in a giant corporation. Allocating capital resources is a process that requires management to identify the various organizational components such as routines, parochialism, attention to issues, and discretionary behaviors of action controlling major uncertainties.

A third major critical contribution made by sociologists deals with rationality, optimality, and efficiency. Landau (1969) argues that redundancy within a firm or a public agency is not a liability – a symptom of waste and inefficiency – but a fundamental mechanism of reliability production. Duplication and overlap provide solutions for action taking in general. The breakdown of one part does not penalize the whole system. The arrogance of a subsystem controlling a monopoly on a problem or a function is diminished. Duplication and overlap may create political conflicts. They also generate conditions for communication, exchange, and cooperation. They lower risks. Organizations are not self-evaluating entities. They tend to substitute their own knowledge for the information generated by their environment. Economic efficiency and optimality as defined by economists are normative enterprises.

Such sociological contributions therefore question three fundamental postulates of the classical theory of administration: the ability of the center or the top, which has the monopoly of authority, to control the agenda of the whole organization by designing formal structures and rules; the fact that the organization functions like a serial or linear machine, in which what happens at the periphery is fully determined by the center; and the expectation that membership makes a difference. In fact, it may well happen that those who have full authority control and exert not much power, while those who have no hierarchical authority in fact have the power and these autonomous actors produce and shape the actual outcomes and policies; in such situations, there is not much continuity between the top and the bottom, and formal limits do not make a difference. Implicit in this view of the organization is the assumption that organizational actors, either persons or subunits, possess preferences and influence

resources that include position or office, functional or professional expertize, side payments, and the like. Because organizations are action arenas driven by power dynamics, administration therefore is the art and craft of generating strategic behaviors. The levers of rewards and sanctions, to align individual behavior and collective goals, rely upon specific incentives, whether social (status, autonomy, etc.), organizational, or financial, and relate to vested interests of various sorts. Designed poorly, incentives may produce subunit conflict and poor firm performance.

Administration as Moral Community Building

While the behavioral revolution still remains a most influential perspective, social sciences have explored alternative perspectives to understand administration processes in organizations. Another view of administration, while still assuming that organizational actors hold resources that may drive decision making, differs from the first view, however, by relaxing the assumption of strong preferences for specific action outcomes.

A series of studies underline the importance of cultural effects (Hofstede, 1980). More specifically, they provide evidence that within the same firm very different patterns are shared across the various countries in which its units or subsidiaries are located as far as values, norms, and attitudes linked to administrative processes and behavioral practices are concerned. For instance, in certain countries, bypassing the hierarchy is considered as a moral sin, while in other countries it is considered as appropriate. Leadership styles considered as acceptable or efficient here are considered as nonappropriate or noneffective there. In other terms, national culture, an exogenous factor, shapes administration in the organization, leaving no room for maneuver except to act in accordance with these cultural macrofactors. Identical phenomena may also be linked to the role played by professions and to the references their members share across organizations, such as MBA-trained managers or the medical professions.

Research nevertheless also shows that organizations as such are not passive but are specific and proactive cultural entities. They carry and mold values, norms, beliefs, and rites even inside the same country. Administration socializes their members as belonging to a specific community that differs from others. Administrators take actions that are designed to help structure more or less plastic preferences. They govern the organization and its members as cultural entrepreneurs. Mechanisms include leadership, especially charismatic leadership; ideology; socialization; recruitment; and environmental constituencies to which individuals have private or professional loyalty. The organization is understood and managed as a moral community. Common to all these mechanisms is the attempt to foster identifications and loyalties, the normative order providing the integrative backbone of the organization. Administration is about forging and changing values, norms, and cognitive characteristics: it may also have to do with preaching and educating.

The role of administrators in structuring preferences is documented by a set of literature on missionary, professional, and community organizations. Institutionalization as studied by Selznick (1949) offers a vehicle to mobilize an organization for meaning and action. Knowledge, or interpretations in action, structures the community. The theoretical roots of such an approach relate to two different social science traditions.

Shils (1975) identifies in each society the existence of a center or a central zone that is a phenomenon of the realm of values, beliefs, as well as action. It defines the nature of the sacred and it embodies and propounds an official religion, something that transcends and transfigures the concrete individual existence, the content of authority itself. The periphery in mass society is integrated through a process of civilization. Anthropologists such as Geertz (1973) demonstrate that culture as a collectively sustained symbolic structure is a means of saying something of something. Through emotions, common cognitive schemes or common meanings are learned: they provide an interpretative function, a local reading of a local experience, which is a story the participants tell themselves about themselves.

More recent contributions have laid down perspectives focused specifically around organizations and their administration. Various processes within firms actually play the role of center: brainstorming sessions, informal encounters, networks linking persons across departments and units, socialization mechanisms of newcomers, and so on. Strong centers are able to create rigidity phenomena in terms of cognitive blindness, which is the firm as a community being unable to catch signals emitted by its environment. Kogut and Zander (1996), for instance, treat firms as organizations that represent the social knowledge of coordination and learning: identity lies at the heart of such social systems, which implies a moral order as well as rules for exclusion.

Action-Oriented Cognition Building

Organizations develop endogenous capabilities to reason, analyze, and think. Daft and Weick (1984) propose a model of organizations as interpretation systems that stresses their sociocognitive characteristics more than the economic ones. Interpretation is the process through which information is given, meaning and actions are selected and fulfilled. They produce knowledge of their own. They are not only power arenas or moral and symbolic orders, but also action-oriented language systems. This perspective emphasizes that administration influences the references mobilized by its members, with such references being actually considered as more or less implicit references and criteria for action taking. It also considers an organization as a collective actor that is not a community, as a homogeneous entity sharing identical values, and as a complex pluralistic, polyarchical, or even heterarchical system (a heterarchy is a system of organization replete with overlap, multiplicity, mixed ascendancy, and/or divergent-but-coexistent patterns of relation) (Stark, 2001). An organization and its administration generate knowledge, knowledge that is not a mere representation of the world and the market, and that is more or less biased. It has consequences. Daily interactions and choices at all levels in the organization carry specific modes of thought.

While sociological perspectives such as ethnomethodology, rational choice and individual methodologism, and reflexivity theory give much attention to individual cognitions, by

comparison fewer studies question the postulate that organizations function like passive social robots, and consider their administration as the art and craft of mental 'bricolage.' Administration in organizations develops abilities to understand what their members do while they do it. They have good reasons to make errors, to the extent that prejudices and beliefs result from ways of reasoning in a logical manner.

Interpretative processes are produced in a collective way (Eden and Spender, 1998). Cognitions generate and diffuse knowledge that is both substantial and procedural. They drive behaviors, providing coordination and cooperation. Specific and evolving languages for action connect the ambitions of the organization and administrative acts, headquarters and operational units, and upstream and downstream functions and tasks (Michaud and Thoenig, 2003). Sharing a common language does not imply that within and across an organization, a uniform and identical set of references is prevalent that is the same for every part or member. Shared means that in interactive situations, use is made of cognitive references and causalities that are compatible (i.e., that link one with another). Such is the case in firms and also in intergovernmental organizations (Schemeil, 2011). Cognitions in action provide implicit decision criteria. They define causal relationships, choice indicators, and time and space horizons.

Two different sources of languages exist. Exogenous languages come from third-party sources, from the exterior of the interactive social body: they are imported as kits, for instance, by hiring professionals such as marketers or controllers. Endogenous languages are codes through which content is constructed by the organization itself. They may not be in line with references or beliefs dominant in the environment. Administration generates practical theories and performative abilities. As a legitimate source, it sets up transitory arrangements between different functional and professional requirements. It defines principles, and it also transgresses them. Administration constructs specific senses, interpretations, and theories of action. Organizations are cognitive and interpretative islands in societies and economies (Koza and Thoenig, 2003).

When Societal Dynamics Impose Administration Regimes

Administration may also be considered as an exogenous rationale whose content is modeled by societal trends and imposed by macroforces. Organizations therefore are not at all local orders of their own. Administration is to be understood as the acts and nonacts of actors who are agents or servants of principals that are out of reach of the organizations: professional communities (engineers, lawyers, doctors, etc.), elites such as Oxbridge and French Grandes Ecoles alumni, administration trends and fads such as modern management and New Public Management, and so on.

In social sciences, this holistic perspective is in line with an old tradition. Such is the case with the concept of the iron cage developed in the very early 1900s by Max Weber (Weber et al., 2002). In this belief, societal, if not global ideologies, for instance, linked to religion or to civil society values, integrate organizations along identical postulates and norms. Administrators adopt the beliefs they induce about action and representation of the world because they prefer to conform rather than to deviate. Therefore, mesolevel-generated change or innovation not only is risky for themselves and for their organization, but also is experienced as a moral sin or social extravaganza.

This sociological tradition overemphasizing deterministic approaches of administration remains quite lively at the beginning of the twenty-first century, partly as an attempt to challenge political economics as a discipline in order to explain how and why economic forms of exchange such as markets operate and evolve, in particular, at the time of rapid globalization of economies and polities.

For instance, sociological institutionalism underlines the importance of constraints such as legitimacy imperatives shared by national teacher associations, with specific local context variations relegated to the background (Meyer and Scott, 1983). Organizational sociologists note the existence of populations of organizations, firms, and nonprofit organizations operating in an identical sector (wineries, newspapers, museums, regulatory bodies, etc.) that adopt identical formal structures, policy ambitions, or inner surveillance rules that are considered as legitimate or as best practices in the field in which they operate (DiMaggio and Powell, 1983). Coercive, normative, and imitative types of isomorphism are driven by the fact that organizations and their administration expect to gain the trust and support of the stakeholders they depend on to achieve their goals. To a large extent, administration as a construction of symbols is linked to messages that are transmitted by certification agencies, global standards, and regulations, when not consulting companies (Brunsson and Jacobsson, 2000). Nevertheless, globalization does not mean that local orders do not matter any longer and that administration at the mesolevel (when not at the microlevel) becomes residual (Sorge, 2005).

A more radical school of thought considers administration at the local order as a mere artifact, as an agent of dominant social classes. Since the end of the twentieth century, a new iron cage is in command in which administration implements postbureaucratic approaches.

This critical school considers that modern management, as a professional reference and as a set of local practices, basically expresses the interests and pressures of neocapitalism's dynamics and pressures. Shareholder value creation is the ultimate goal to satisfy. Business school education and research provide tools and legitimacy to a new set of methods to incentivize and control members of an organization. Short-term and quantitative performance indicators should only be considered, due to the members of the organization being driven by greed, and this is expected to apply from top to down all along the authority hierarchy. Any knowledge supplied by social sciences is considered as irrelevant for organizational administration: individuals and groups behave with a rationality that is close to the postulates on which microeconomics is based.

This radical approach describes administration as a domination regime. Contrary to polyarchic regimes, oligarchic forms of power overemphasize hierarchy of authority and top-down approaches as legitimate governance processes. They make no room for deliberation and discussion. Blind allegiance to the rules is expected from the rank and the file. But this domination

is administered in a soft manner, and not by coercion or raw force. While the discourse keeps making reference to processes such as decentralization, quality of working life or participation, or self-actualization, in practice what is expected is that individuals and groups appropriate the goals and pressures emitted by their hierarchy as being rational and making sense for themselves. Symbolic violence is the name of the game (Courpasson, 2006).

Administrative Law: The United States and Beyond

Cary Coglianese, University of Pennsylvania Law School, Philadelphia, PA, USA

Abstract

Administrative law constrains and directs the behavior of officials in the many governmental bodies in every country responsible for implementing legislation and handling governance responsibilities on a daily basis. This field of law consists of procedures for decision making by these administrative bodies, including rules about transparency and public participation. It also encompasses oversight practices provided by legislatures, courts, and elected executives. The way that administrative law affects the behavior of government officials holds important implications for the fulfillment of democratic principles as well as effective governance in society.

Administrative law refers to the body of rules and procedures affecting government agencies as they implement legislation and administer public programs. Yet it is also much more than just rules and procedures. Administrative law applies to the ongoing operation of government bodies and seeks to shape official decisions that impact businesses and citizens throughout society. These decisions include granting licenses, dispensing government benefits, conducting inspections and investigations, imposing sanctions, issuing orders, awarding contracts, collecting information, hiring employees, and even making still further rules and regulations that apply to both governmental and private actors. Administrative law affects all of these varied decisions and addresses fundamental questions about how government authority can and ought to be exercised. It implicates society's most deep-seated political and moral values: democracy, equity, efficiency, privacy, transparency, and justice. And it does so by intervening in complex and diverse organizational environments within which public and private actors face varied, often shifting, motivations, incentives, and constraints. A proper study of administrative law therefore requires immersion in a wide breadth of issues in social science: normative as well as positive political theory; individual as well as organizational behavior; and law as well as politics, sociology, public administration, and economics.

Even when it is just considered as a body of rules, administrative law is complex. It draws its legal pedigree from a variety of sources: constitutional law, statutory law, internal policy, and, in some countries, common law. Government agencies' organizational structures and routines are shaped by provisions derived from both generic procedural statutes (such as, in the US, the Administrative Procedure Act) and statutes addressing specific substantive policy issues such as energy, education, taxation, or welfare benefits. This array of legal sources means that administrative rules and procedures can vary significantly across agencies and, even within the same agency, across discrete policy issues or types of actions.

The social science study of administrative law seeks to make sense of the complexity of administrative law and how it shapes, and is shaped by, the organizational environments within which it operates. Research has proceeded not only to test theoretical propositions about whether and how legal norms and institutions influence administrative behavior but also to identify and help solve applied problems. Administrative law research is characterized in part by prescriptive efforts to design rules that better promote political and social values, and in part by empirical efforts to explain how law influences the behavior of government agencies. Government agencies often possess considerable policy discretion but are staffed by unelected officials, so a key objective for administrative law scholars has been to understand how agency officials are, or can be, held democratically accountable (Lodge and Stirton, 2010). Administrative law places particular emphasis on the empirical understanding of the impact of courts and other oversight bodies – as these entities purport to hold administrators accountable to elected officials and the publics they represent. Although administrative law scholarship has a rich and important tradition of doctrinal analysis, the insights and methods of social science have become essential for understanding how administrative law and legal institutions can affect democratic governance. By drawing on social science methods to understand how legal rules and institutions affect governance, administrative law scholarship aspires both to inform and to improve the outcomes of public institutions.

Administrative Law and Democracy

Administrative agencies make decisions affecting citizens' lives and entire industries – but these agencies are usually staffed by officials who are neither elected nor otherwise directly accountable to the public. A fundamental challenge in both positive and prescriptive scholarship has been to analyze administrative decision making from the standpoint of democracy. This challenge is particularly pronounced in constitutional systems with executive bodies that are formally separate from the legislature and where political party control can be divided between the branches of government, as in the US. But the general challenge applies anywhere because of the enormous discretion afforded to unelected administrative officials. Much work in administrative law aims either to justify administrative procedures in democratic terms or to analyze empirically how those procedures can effectuate democratic values.

A common way to reconcile decision making by unelected administrators with democratic principles has been to consider administrators as mere implementers of decisions made through a democratic legislative process. Under what is sometimes called the 'transmission belt' model of administrative

law, administrators are treated as mere instruments used to implement the will of the democratically controlled legislature (Stewart, 1975). Statutes serve as the 'transmission belt' to the agency, both transferring democratic authority to administrative actors and constraining those actors so that they advance legislatively approved goals.

As a positive matter, the 'transmission belt' model underestimates the amount of discretion held by administrative officials. Statutes are seldom self-executing. They need interpretation and must be applied in myriad concrete circumstances. In interpreting and applying statutes, administrators assume discretion. Statutes do not always speak clearly to the varied circumstances that confront administrators. Not only are many of these circumstances unanticipated by legislators, but elected officials often may lack incentives for making laws clear or precise in the first place, as it can be to their electoral advantage to appear to have addressed vexing social problems only in fact to have passed difficult policy questions and tradeoffs along to unelected administrators. For some administrative tasks, particularly monitoring and enforcing laws, legislators give administrators explicit discretion over how to allocate their agencies' resources to pursue broad legislative goals.

Scholars disagree about how much discretion legislators ought to allow administrative agencies to exercise. Minimalists, emphasizing the electoral accountability of the legislature, have urged that any legislative delegations of authority to agencies be narrowly constructed (Lowi, 1979). Those scholars of a more expansionist bent emphasize administrators' indirect accountability to elected officials and contend that legislatures themselves are not perfectly representative, especially when key decisions are delegated internally to committees and legislative staff (Mashaw, 1985). While the optimal amount of authority to be delegated to agencies remains a subject of analysis (Stephenson, 2008), in practice administrative agencies continue to possess considerable discretion, even under relatively restrictive delegations.

Given that agencies do possess discretion, one aim of administrative law has been to identify procedures that encourage administrators to exercise their discretion in ways that promote both procedural and substantive values. A leading approach has been to design administrative procedures to promote broad public participation, including representation of a wide array of interest groups (Stewart, 1975). Transparent procedures and opportunities for public input give organized interests and ordinary citizens an ability to represent their views in the administrative process. Such procedures include those providing for open meetings, access to government information, hearings, and opportunities for public comment, and the ability to petition the government. Transparency and participation requirements are defended not only on the grounds of procedural fairness, but also because they are expected to deliver more information to administrators before they make decisions. These procedures may also protect against regulatory capture – the much-decried predicament where an agency's decisions come to promote an industry's private interests to the exclusion of the broader public interest (Stigler, 1971).

Although certain requirements, such as the notice-and-comment procedure followed by US agencies when making rules, provide the public with the opportunity to participate in administrative decision making, this does not necessarily mean that any extensive or representative portion of the public actually participates in administrative policymaking. Nor does it mean that public participation has any significant impact on agency decisions. In the US experience, most agency rulemaking proceedings garner only a small number of comments – and in most rulemakings by far the largest number of these are submitted by businesses or other organized groups rather than by what might be considered ordinary members of the public (Coglianese, 2006). On occasion, however, agencies will issue high-salience rules that do garner thousands of comments – typically short, unsophisticated expressions of preferences rather than comments conveying substantive information.

As to whether comments, simple or sophisticated, make a difference, the answer appears to be at most 'sometimes.' Studies find varying degrees of association between arguments presented in comments and changes made to proposed rules (West, 2004; Yackee, 2005; Shapiro, 2008). Formal comments, though, are submitted only after agencies have invested much staff time in developing their proposed rules, a point at which much analysis and decision making has already been completed. For this reason, representatives of organized interest groups often seek to influence administrative policy by making informal contact with officials well before the agency proposes a rule and invites formal public comments (Furlong and Kerwin, 2005). Interest group representatives may also continue to remain involved with the agency after a 'final' decision has been made. Whether through litigation or further discussions, agencies can be persuaded to issue amendments or make other policy changes to otherwise final rules (Coglianese, 1996; West and Raso, 2012).

The widespread use of the Internet has generated interest in so-called e-rulemaking, or the use of information technology to connect the public more closely with the work of administrative agencies. The advent of agency web sites has put much more extensive information about administrative matters at the fingertips of users around the world (provided, of course, individuals can easily navigate through all the extraneous information also taking up space on agency web sites) (Coglianese, 2013). Agencies now routinely accept public comments submitted by email, and many also have a presence on social media sites like Facebook and Twitter (Coglianese, 2013). In the US, the federal government has created a one-stop web site called *Regulations.Gov* which indexes agency regulatory proceedings, houses supporting documents and previously submitted public comments related to new rules, and provides a button for users to submit comments on proposed rules. Although many early advocates of e-rulemaking heralded technology's promise to expand public participation in the regulatory process, to date it appears that the patterns of commenting on agency rulemaking remain largely unchanged (Balla and Daniels, 2007).

It should not be surprising that levels of public participation in rulemaking remain relatively low, as the subject matter of much administrative action remains high in complexity or low in salience – or both. However, technology has undoubtedly made it easier for elites inside and outside of government to monitor what agencies are doing, as well as for scholars of administrative law to study more systematically how

administrative rules and procedures may better serve democratic principles.

Courts and Judicial Review

Concern about democracy also undergirds administrative law's emphasis on judicial review of government action. Under well-accepted legal principles, courts serve as key enforcers both of the substantive laws that government officials are charged with implementing as well as the procedural requirements that these same officials must follow in their implementation of substantive laws. Courts have also imposed their own additional procedures on administrators based on constitutional and sometimes common law principles. A key normative question has centered on how aggressive courts should be when it comes to reviewing the actions of administrative agencies.

Administrative agencies typically possess a greater capacity for making sound technical and policy judgments than do courts. Even in legal systems with specialized administrative courts, not only do agency officials and their staffs possess greater policy expertise than judges but administrators are also often more closely connected to democratic institutions than judges. These considerations have long weighed in favor of judicial deference to administrative agencies, lest judges disregard either the technical expertise or the political legitimacy reflected in many administrative decisions. On the other hand, it is also generally believed that some credible oversight by the courts bolsters agencies' compliance with administrative law and may improve their overall performance. The prescriptive challenge has been to identify the appropriate degree of deference for courts to give to agencies overseeing their decision making.

Sometimes the degree of deference is said to depend on whether agencies are making factual, policy judgments as opposed to making judgments about the meaning of the law. Courts might have grounds for giving more deference to agencies' policy judgments, simply ensuring that they have followed transparent procedures. Yet courts have also been known to take a careful look at policy decisions to see that they are based on a thorough analysis of all relevant issues. The latter approach is sometimes referred to as 'hard look' review in the US, as it calls for judges to probe carefully into the agency's reasoning to ensure that agency officials conducted a thorough analysis of policy options before reaching a decision. Although one might suspect courts would give less deference to agencies' legal interpretations than to their factual judgments, especially when agencies must interpret their own governing legislation, one of the most widely cited US Supreme Court opinions calls upon courts to defer to agency interpretations of ambiguous provisions within the statutes they implement (*Chevron v. Natural Resources Defense Council*, 1984). Prescriptive scholarship seeks to provide analytic guidance for judges on the appropriate level of deference that they should give to both legal and policy choices made by agencies (Zaring, 2010).

The proliferation of prescriptive doctrinal principles in contemporary legal systems gives rise to the question of what impact administrative law has on the actual decision making of judges in deciding cases. After the US Supreme Court issued its *Chevron* decision, lower courts reportedly shifted to deferring more to agency interpretations (Schuck and Elliott, 1990). Yet legal principles, whether articulated by the Supreme Court or reflected in laws adopted by the legislature, are only one factor that may explain how judges make their decisions. Just as administrators themselves possess residual discretion, so too do judges possess discretion in deciding how deferential to be to administrative agencies' policy and legal determinations. As in other areas of law, political ideology also may help explain patterns of judicial decision making in administrative law cases (Revesz, 1997; Miles and Sunstein, 2006).

In addition to analyzing judicial decision making, the field of administrative law has been centrally concerned with the impact of judicial review on the behavior of officials within administrative agencies. Normative arguments about judicial review typically depend on empirical assumptions about the effects courts have on the behavior of administrative agencies. Indeed, much legal scholarship in administrative law builds on the premise that judicial review, if deployed properly, can improve governance (Edley, 1990). The effects often attributed to judicial review include making agencies more observant of legislative mandates, increasing the analytic quality of agency decision making, and promoting agency responsiveness to a wide range of interests. Administrators who know that their actions may be subjected to review by the courts can be expected to exercise greater overall care, presumably making better, fairer, and more responsive decisions than administrators who are insulated from direct oversight.

Notwithstanding these purported beneficial effects from judicial review, scholars have also emphasized courts' potentially debilitating effects on agencies. They have widely accepted, for example, that administrators in the US confront a high probability that their actions will be subject to litigation. Cross-national research suggests that courts figure more prominently in government administration in the US than in other countries (Kagan, 2003). The threat of judicial review purportedly creates significant delays for agencies seeking to develop regulations (McGarity, 1992).

In some cases, agencies have been said to have retreated altogether from efforts to establish regulations. The US National Highway Traffic Safety Administration (NHTSA) is usually cited as the clearest case of this so-called ossification effect, with one major study suggesting that NHTSA has shifted away from developing new auto safety standards in order to avoid judicial reversal (Mashaw and Harfst, 1990). Other research, however, indicates that the threat of judicial interference in agency decision making has been significantly overestimated. Litigation challenging administrative action in the United States occurs less frequently than is generally assumed (Coglianese, 1997), and some research indicates that agencies can surmount seemingly adverse judicial decisions to achieve their policy objectives (Jordan, 2000). Large-sample studies have failed to confirm the view that judicial review significantly obstructs the rulemaking process in the United States (O'Connell, 2008; Yackee and Yackee, 2010).

Concern over excessive adversarialism in the administrative process persists in many countries. Government decision makers have at times pursued collaborative or consensus-based processes as alternative strategies for creating and implementing administrative policies. In the US, an innovation called negotiated rulemaking has been used by some administrative

agencies in an effort to prevent subsequent litigation. In a negotiated rulemaking, representatives from government, business, and nongovernmental organizations work toward agreement on proposed administrative policies (Harter, 1982). In practice, however, these agreements have not reduced subsequent litigation, in part because litigation in the US over agency rules has ordinarily occurred much less frequently than generally assumed (Coglianese, 1997). Moreover, even countries with more consensual, corporatist policy structures experience litigation over administrative issues, often because lawsuits can help outside groups penetrate close-knit policy networks (Sellers, 1995). In pluralist systems such as the US, litigation is typically viewed as a normal part of the policy process, and insiders to administrative processes tend to go to court at least as often as outsiders (Coglianese, 1996).

Overall, the impact of the judiciary on administrative governance has been and will remain a staple issue for administrative law. Empirical research on the meaning and impact of litigation in an administrative setting has the potential for informing prescriptive efforts to craft judicial principles or redesign administrative procedures in ways that contribute to more effective and legitimate governance.

Legislative and Executive Oversight

In addition to the judiciary, other governmental institutions oversee the work of government agencies and may have a significant impact on administrative governance. In the US, given its system of separate branches of government, administrative agencies find themselves on the receiving end of pressure from both legislative and executive officials. Much empirical scholarship on administrative law has investigated oversight mechanisms and how they affect behavior within administrative agencies.

An influential political economy theory treats the procedures imposed by legislative and executive overseers as mechanisms of control deployed to influence agency outcomes (McCubbins et al., 1987). According to this approach, administrative law addresses the inherent principal–agent problem confronting elected officials when they delegate power to unelected administrators. Administrators inevitably face incentives to implement statutes in ways that may stray from the goals intended by the coalition that enacted the legislation. Yet it is difficult for legislators and others to monitor agencies continually and, in any case, a law's original enactors do not remain in power forever. Elected officials therefore have good reason to create administrative procedures with the goal of entrenching the outcomes desired by the original coalition. Empirical research, however, suggests that administrative procedures provide at best only limited tools for locking in the enacting coalitions' preferences (Balla, 1998). Agencies may be less faithful to the enacting coalition's interests because they are more responsive to the politics of the moment than their institutional independence might suggest. Some analysis suggests that agencies are actually better reflective of current public preferences than are legislatures or elected executives (Stephenson, 2008).

An overarching question in research on legislative and executive oversight is whether officials from either legislative or executive bodies exert the greater degree of influence over administrative agencies. One school of thought posits legislative dominance in the oversight of US agencies, whether through the legislation they adopt, their control of agency budgets, or their ability to hold hearings or launch investigations (Weingast and Moran, 1983). Another school of thought holds that presidents exert more influence, whether through their powers to appoint the heads of agencies, direct agencies to comply with internal management and analytical requirements, or take the leading role in negotiations over agency budgets (Moe and Wilson, 1994). Given that agencies operate in a complicated political environment in which they are subject to multiple institutional constraints and pressures from both legislators and executive officials, the existing evidence seems to provide support for both schools of thought. It is clear, in other words, that both presidents and legislative officials exert influence over agencies, even if neither exercises complete control over administrative action.

One way legislatures have sought to influence agencies has been to try to direct their policymaking agendas. Not only can a legislature shape the direction of an agency by how it structures its delegation of substantive authority, but a legislature can also exert influence on the timing of administrative action. Statutes can contain deadlines for agency action, imposing a legal obligation on agencies to develop implementing rules by a specified time. Only a minority – perhaps even only a small fraction – of all regulations in the US are established under the stricture of a statutory deadline (West and Raso, 2012; Gersen and O'Connell, 2007). However, the legislature still prompts the initiation of many more administrative regulatory proceedings in the US than do executive branch officials or the courts (West and Raso, 2012). The imposition of deadlines also appears to speed up the regulatory process, at least modestly (Gersen and O'Connell, 2007).

Once an administrative agency decides to initiate a regulatory proceeding, in many jurisdictions the agency must conduct a regulatory impact analysis that will be reviewed by either a legislative or executive branch oversight body (Wiener, 2013; Radaelli and de Francesco, 2010). In the US, every president since Ronald Reagan has imposed a requirement that agencies develop regulatory impact analyses for their most significant administrative rules. Such mandated analyses must be reviewed by a White House office called the Office of Information and Regulatory Affairs (OIRA), an oversight body that has been extensively debated by administrative law scholars. The dominant theory is that presidents use the OIRA oversight process to coordinate regulatory priorities and resolve the principal–agent problem that exists between the president and those appointees the president selects to head regulatory agencies. As a normative matter, proponents of legislative supremacy decry the encroachment of presidents on the work of agencies that possess authority delegated to them by statute. Presidentialists, on the other hand, favor OIRA review as it offers a mechanism for the one official elected in a nationwide election to oversee the ongoing work of dozens of agencies that issue hundreds of important rules every year. OIRA oversight, based as it is on economic analyses that agencies prepare, has also triggered normative debate over the use of benefit–cost analysis in administrative policymaking. Advocates claim that benefit–cost analysis helps improve regulatory policy, while

opponents claim it only obfuscates decision making and delays much needed rules. Concern also exists that business interests use the OIRA process as a backdoor means of influencing regulatory policy to the detriment of achieving statutory goals or advancing the overall public interest.

Empirical researchers have been motivated by the normative debate over the OIRA process. They have documented that modern presidents have indeed sought to use OIRA review to achieve goals consistent with their policy priorities, even if these may not always comport with the results of benefit–cost analysis (Shapiro, 2005). Researchers have also shown that, in practice, OIRA review manifests itself differently across different administrations, especially in the degree to which interactions between White House and agency staff are cooperative or adversarial (West, 2006; Croley, 2003). Notwithstanding OIRA's prominence, agency staff members continue to report that they retain considerable discretion in framing and making many regulatory policy decisions, even ones formally subject to OIRA scrutiny (Bressman and Vandenbergh, 2006). Furthermore, the economic analysis produced as part of the OIRA review process appears to have much less impact on decision making than many advocates of benefit–cost analysis have hoped (Hahn and Tetlock, 2008) – but also much less of an impact in terms of delaying regulatory output as opponents of such analysis have feared (Coglianese, 2008).

Administrative policymaking occurs within a complex political and legal environment, one in which legislatures and high-level executive officials clearly play important roles. However, even major oversight entities do not possess the high degree of control that their proponents desire or their critics fear. An ongoing challenge for administrative law research remains to explain better the precise effects of legislative and executive oversight under varied conditions.

Administrative Law and Governance

Administrative law lies at several intersections, crossing the boundaries of law and politics, political theory and political science, public law, and public administration. As the body of law governing governments, the future of administrative law rests in expanding knowledge about how law and legal institutions can advance core political and social values. A concern with democratic principles will continue to dominate research in administrative law, as will interest in the role of judicial, legislative, and executive oversight in improving administrative governance. Yet administrative law can and should expand to meet new roles that government will face in the future. Ongoing efforts at deregulation and privatization may signal a renegotiation of the divisions between the public and private sectors in many countries, the results of which will undoubtedly have implications for administrative law. Administrative law also now functions in an increasingly globalized and digital world, with the emerging application of both international administrative institutions and new uses of technology that might advance both public legitimacy and policy effectiveness – or that might undermine or support administrative law institutions. No matter where the specific challenges may lie in the future, social science research on administrative law will continue to be needed to understand the operation of governmental institutions and identify ways to design rules and procedures that can potentially increase social welfare, promote the fair treatment of individuals, and expand the potential for transparent and democratic governance.

Abstract

The sociological study of adolescence seeks to understand it as a socially constructed stage in the life course and to explain the social factors that shape adolescents' behavior, orientations, and socioemotional well-being. As a life stage, adolescence is characterized by semi-independence. The ages at which individuals enter and exit adolescence are historically and culturally situated and the boundaries are thought to be currently shifting, lengthening the period overall. The family, schools, peer group, workplace, and neighborhood are critical institutions and contexts shaping adolescent development, though sociologists also view adolescents as actors that help create the norms and contexts in which they live. Recent scholarship reflects a growing interdisciplinary approach to the study of adolescents, bringing together social science with biological and genetic approaches to understanding human behavior.

Introduction

Psychologist G. Stanley Hall (1904) popularized the term 'adolescence' early in the twentieth century, though it did not become a major area of research for social scientists until midcentury. Early on, the study of adolescence was dominated by the study of the 'problems' of adolescence, and the period itself was viewed as inherently tumultuous. Though problem behaviors (e.g., delinquency) are still of great interest and scholars tend to characterize even other behaviors in terms of their risk (e.g., a conceptualization of sex as inherently risky or only focusing on its riskier behaviors such as contraceptive nonuse), sociologists have also extensively examined prosocial behavior (e.g., volunteerism) and a range of behaviors and orientations theorized to promote status attainment and well-being in adulthood (e.g., academic performance, occupational aspirations). Indeed, adolescence is often characterized as a critical period in the process of adult educational attainment and occupational pathways.

The sociology of adolescence is principally concerned with understanding adolescence as a life stage, as well as explaining the experiences and behaviors of adolescents as social beings. As a life stage, sociologists study cultural notions characterizing adolescence as well as the structural forces defining its nature and its boundaries with contiguous life stages: childhood and adulthood. In this way, adolescence is an interrelated set of ideas that are culturally and historically situated. With respect to the study of adolescents' experiences and behaviors, sociologists primarily examine how institutions and other social factors shape adolescents' behavioral and socioemotional well-being. The ways in which adolescents create and change the social world around them garners less attention, but is also fundamental to a sociological understanding of adolescence.

Adolescence as a Life Stage

Adolescence is generally defined as a period of the life course characterized by semidependency. Adolescents have greater autonomy than children, but not the full rights and responsibilities of adulthood (Crosnoe and Johnson, 2011). As a social construction, it is subject to change over time and varies across societies. Adolescence in the contemporary United States is largely conceived of as a time of identity development and preparation for adulthood.

The beginning of adolescence is often marked by the onset of puberty, a biological process, though the social meaning of it varies across contexts. Its end is usually marked by the assumption of adult roles, which in Western industrialized societies tends to include residential independence, completing schooling, marriage, parenthood, and full-time employment. The development of responsibility for oneself and others is also recognized as defining adulthood and tends to go hand-in-hand with role assumption, though these can occur separately (e.g., a teen parent who has not embraced the responsibilities of the parent role). The study of connections between adolescence and other life stages has been facilitated by longitudinal data collections following children into adolescence and adolescents into adulthood (e.g., Kindergarten Cohort of the Early Childhood Longitudinal Study and the National Longitudinal Study of Adolescent Health in the United States, the 1958 National Child Development Study in Great Britain).

The boundaries of adolescence, particularly its upper boundary with adulthood, are structured by formal and informal norms prescribing and proscribing behavior. Formal norms include laws delineating ages when young people become responsible for their own behavior (e.g., are criminally responsible; contracts can be enforced) can leave school, vote, drive, drink alcohol, marry, and so on. Informal norms help define adolescence as well. For example, norms against nonmarital pregnancy are stronger in relation to adolescence than adulthood, though even for adolescents there is racial/ethnic and socioeconomic status variation in norms (Mollborn, 2009).

Adolescence is also tied to and structured by social institutions that are themselves historically and culturally situated (Shanahan and Macmillan, 2008). For example, factory jobs increasingly available during industrialization allowed earlier economic independence among young people, facilitating entry into adulthood. Likewise, a strong economy and significant public spending in the post–World War II period in the United States (e.g., subsidized higher education, federal backing of home loans, etc.) enabled a much more rapid move into economic self-sufficiency for young people and accompanying movement into residential independence, marriage,

and child rearing at relatively young ages. During periods when educational investments in age-segregated institutions expanded, such as when high schools became more universal, adolescence has been extended into older ages. Similarly, age restrictions on employment and certain job duties have pushed the boundaries of adolescence upward at times.

Currently, scholars suggest that the boundaries of adolescence are again shifting. On the lower end, the age of puberty has dropped over time (Herman-Giddens, 2007). To the extent physical maturation elicits different responses from others, including greater autonomy granting by parents and expectations of 'adolescent' behavior by adults and peers, the beginning of adolescence may be dropping. Advertising trends and the advent of digital media are also topics explored by sociologists considering whether children's transition to adolescence may be shifting to younger ages. The upper boundary is in question as well. With major restructuring of the economy, including the rising wage premium to college and graduate degrees relative to lower education levels, economic self-sufficiency is taking longer to achieve (Settersten et al., 2005). Young people are staying in school longer, and are delaying marriage and full-time work. Those not pursuing higher education are often working in jobs that cannot support a family. Pathways in the transition to adulthood are becoming more diverse as well in terms of the ordering and timing of role transitions as well as involving more frequent reversals (e.g., going back to school, moving back to the parental household). Whether young people are pursuing higher education or working in low-paying jobs, their parents are often contributing substantial financial support during their 20s and into their 30s (Settersten et al., 2005). How these demographic changes observed over the past several decades have been discussed in relation to adolescence as a life stage is a key place of divergence between the fields of sociology and developmental psychology. Whereas developmental psychologists have more readily embraced recognition of a new life stage between adolescence and adulthood, referred to as 'emerging adulthood,' sociologists have characterized these changes as extending adolescence or as lengthening and diversifying the transition from adolescence to adulthood.

Social Institutions and Contexts Shaping Adolescent Development

In addition to the study of adolescence as a life stage, sociologists seek to understand adolescents' behavior, orientations, health and well-being, here referred to under the broad conceptual umbrella of development. Sociological explanations for development focus on the practices, values, and organization of other major social institutions and the larger social contexts in which adolescents live. Most research focuses on single institutions or contexts, including the family, peers, schools, work, and neighborhood. Research at the nexus of these is emerging however.

Family

A key part of adolescence involves a renegotiation of parent and child roles as young people gradually seek and are granted more autonomy. While early scholarship assumed high levels of conflict between adolescents and their parents during this period of growing independence, research consistently demonstrates that adolescents maintain close relationships with parents as they develop. Conflictual relationships remain an exception to the rule. Furthermore, while peers become a more important part of adolescents' lives, parents' behavior and parent–child relationships remain influential (Crosnoe and Cavanagh, 2010; Giordano, 2003).

Research consistently shows that adolescents' whose parents provide high levels of support and avoid harsh punishment, and who monitor their behavior, have better emotional, academic, and behavioral outcomes. These parenting practices have been shown to be beneficial across racial/ethnic groups, though recent research also suggests that what can appear to primarily White scholars as too controlling or harsh parenting may not be as harmful to minority adolescents as it is to Whites (Crosnoe and Cavanagh, 2010).

Parents' marital status is also linked to a range of adolescent behaviors, orientations, and experiences (Amato, 2010; Sweeney, 2010). Significant demographic changes in family life, including the rise of divorce, nonmarital childbearing, and cohabitation, have diversified family life in key ways. Whether parents are never-married singles, cohabiting, married, or divorced is associated with family economic resources, parental time availability, and parenting behaviors including parental support and monitoring (Amato, 2010; Sweeney, 2010). Importantly, static cross-sectional comparisons hide important differences in adolescents' longer term experiences of their parents' marital histories. Apart from marital status at a given time point, family structure instability is associated with deleterious outcomes for adolescents, including greater delinquency, lower academic performance, and instability in adolescents' own romantic relationships. Stress is thought to cumulate across family structure transitions due to changes in family composition and parenting behavior as well as disruptions in school and neighborhood relationships.

Peers

Compared with childhood, friends tend to have greater influence on behavior and orientations in adolescence, and peer relationships are more complex (Crosnoe, 2000). Friends, and peers more broadly, are theorized to influence one another by serving as examples to each other and through setting and reinforcing social norms. Isolating the effect of friends' behaviors or attitudes on adolescents has proven challenging, however, as adolescents often select friends with similar characteristics and behavior as their own. The nature of friendships, that is whether they are close, supportive, conflictual, and so on, also affects adolescent well-being (Giordano, 2003) and may serve to qualify friends' influence. As with other social relationships, stronger attachments are thought to magnify social influence.

Social network approaches to studying friend influence have focused on characteristics of friends in the network as well as friendship network properties themselves. For example, adolescents whose friends are engaged in more delinquent behavior report greater delinquency themselves, but this association is stronger in dense (closely knit) friendship networks than in less cohesive ones, and is stronger for adolescents who

hold a more central place in their network than those whose place is more peripheral (Haynie, 2001).

Peer networks are often studied through friend nominations – in which adolescents identify with whom they are and are not friends. Crowds are a larger grouping of peers that involve both friendships and acquaintances and typically contain multiple friendship networks (Crosnoe, 2000). Frank et al. (2008) also examine peer relationships by identifying clusters of students taking sets of courses that differentiate them from other students. They argue that these groups of students form a social context (which they call local positions) in which students observe, make comparisons, and transmit information and expectations, shaping their academic behavior. For girls, whose math-taking decisions are thought to be more susceptible to peer influence, levels of math taking in their school and in their local position in the baseline year of the study predicted math advancement over the following year. The effect was strongest, and also extended to boys, at the lowest math levels.

Romantic relationships in adolescence are of developmental significance as well, though scholarly attention has come much later than it did for friendships and peer networks (Giordano, 2003). New for adolescents, they generally involve greater emotionality than friendships, and the norms differ as well, including norms of exclusivity (Giordano, 2003). Despite social change in adolescents' attitudes and behaviors regarding sex, gendered norms continue to operate. Girls still pay a price in terms of peer acceptance when they have multiple sexual partners over time, whereas boys with more partners receive higher peer acceptance (Kreager and Staff, 2009). Romantic relationships can also serve as key links between peer groups. Examining romantic partner's drinking, friends' drinking, and partner's friends' drinking behavior, Kreager and Haynie (2011) find significant effects of partner's friends' behavior on dater's future drinking. Their findings support the claim that romantic relationships connect peer networks, facilitating the diffusion of behavior across them.

Whereas research on friendships tends to emphasize the positive, (Giordano, 2003) and research on peer networks considers both the positive and negative (e.g., promoting proacademic norms, encouraging risk behavior), the study of romantic relationships is dominated by a concern with risk. Studies of romantic relationships focus heavily on sex (framed as problematic), dating violence, and whether romantic relationships undermine adolescents' socioemotional well-being.

At the nexus of families and peers, studies show parents influence the nature of adolescents' friendship networks. For example, Knoester et al. (2006) find parenting practices such as selecting neighborhoods for the quality of schools, parental monitoring, and relationship quality shape the levels of problem behavior (i.e., fighting, deviance) and school-related behavior (i.e., grades, college expectations, extracurricular participation) of friends. Problem behavior in the network is lowest and prosocial behavior is highest when adolescents have high quality relationships with their parents and monitoring is relatively high. Peer support can also compensate for the deleterious effects of lower quality relationships with parents. Rodgers and Rose (2002) found the negative effects of low parental support on emotional well-being (a composite of self-esteem, depressive symptoms, and suicidal ideation) was buffered by peer support, though only in divorced, single parent families.

School

School features such as the sector (private vs public), size, racial and socioeconomic composition, level of economic and social resources, and nature of the assignment system (e.g., school choice) are linked to varying degrees with adolescent achievement, and to some extent adolescent health and socioemotional well-being. Internal organization, including level of curricular specialization and systems of tracking are of interest as well. Whereas earlier systems in the United States, tracked students into global, multiyear positions (e.g., vocational track, college-bound track), tracking is now subject-specific, 1 year at a time, and involves more mobility (Lucas, 1999). Nevertheless, informal and formal links are involved in course progression, especially in subjects such as math. Course pathways, or sequences of courses that groups of students tend to follow, are becoming of interest in the absence of identifiable and static track placements. Of primary concern across eras has been the extent to which placement within the curriculum is based on factors other than prior achievement (e.g., race), ease of mobility within the system (i.e., movement across tracks), and whether placement affects ongoing learning. Lower social class background and being Black or Hispanic are disadvantages in curricular placement, even taking into consideration prior levels of achievement (Lucas, 1999).

Another body of work focuses on issues of school climate and school culture. The climate and culture of schools can be shaped by some of the institutional factors above (e.g., size, racial composition), but are also thought to have independent effects on adolescents. Coleman's (1961) depiction of 'adolescent society' was one of the first, and certainly the most influential, studies of school culture. Coleman argued that lengthy, age-segregated systems of education isolated teenagers from adults and allowed development of a largely separate youth culture, varying some across schools, but generally at odds with mainstream adult values and norms. More recent scholarship characterizes school culture as more complex; involving mainstream as well as oppositional elements, varying in significant ways across schools, and varying in its impact on adolescents given their place in the social system of a school. The level of emphasis on academic achievement in school culture, at the heart of Coleman's concerns, is important for understanding adolescent behavior, but so too are nonacademic aspects. As an example, consider a school's cultures surrounding appropriate body size and weight management practices. High school girls' efforts to lose weight are influenced by the body sizes of other girls in their school, as well as other girls' weight control efforts. Interestingly, while the proportion of overweight and underweight girls in a school overall shapes girls' weight control behavior, efforts to lose weight at the school level are not a factor. It is only the weight control efforts of those of a similar body size that is associated with girls' efforts to lose weight (Mueller et al., 2010).

As noted above, adolescents develop within multiple settings and institutions. How schools contribute to adolescent outcomes alongside and in combination with the influence of families demonstrates this idea well. In their review of this

literature, Parcel et al. (2010) conceptualize the resources of both families and schools in three forms of capital: financial (e.g., parents' earnings, school budgets), human (e.g., parents' education levels, teacher training), and social (e.g., shared norms or social support within families or schools). They emphasize this latter form of capital often includes ties between parents and schools. Importantly, family and school resources can interact to produce adolescent outcomes, sometimes compounding (dis)advantage and other times compensating for a lack of resources in one domain. For example, when it comes to attending selective colleges, Kim and Schneider (2005) find that parents' involvement in school programs on college and financial aid matters most when parents have relatively low education levels. Institutional guidance may compensate for lack of some resources at home. Importantly, the effects of resources in more than one context are found to be additive in some studies – each important but operating independent of one another. Which resources reinforce or substitute for one another across institutions and for what outcomes continues to occupy scholars' attention.

Work

Nearly all US teenagers work during the school year at least at some point during high school, and summer employment rates exceed that of the school year. Whereas at early ages employment is often informal and involves a limited time commitment (e.g., yardwork, babysitting), it becomes increasingly formal and time intensive with age (Mortimer, 2010). Rates of employment have been on the decline recently though. An analysis of 16–17 year olds over the period from 1950 to 2010 indicates an overall downward trend in labor force participation since the late 1970s for this age group, marked by notable drops during recessionary periods that never fully recover (Smith, 2011). Employment rates by gender have been fairly comparable in recent years, but adolescents from disadvantaged minority groups are less likely to be employed than non-Hispanic White adolescents due to reduced opportunity in local labor markets and other structural factors.

The consequences of employment while attending school have been a matter of lively and ongoing debate in sociology and other related disciplines including psychology. Whereas research on families, schools, peers, and neighborhoods tends to focus on variation in structure and dynamics, the study of adolescent work is almost exclusively focused on work status and the amount of time spent working. The evidence accumulating from this effort is conflicting. On the one hand, working a limited number of hours in adolescence is associated with higher grades and positive health behaviors, and working more hours a week has been linked to higher earnings and labor force participation after high school. On the other hand, working more hours has also been linked to higher levels of substance use, problem behaviors, and poor health habits. Employment is argued by some scholars to build human capital and help prepare adolescents for adult work roles, while to others it competes with school and exposes adolescents to stress and situations for which they are developmentally unready. Recent research suggests that the risks and benefits of employment may depend on teens' reasons for working, how they use their earnings, their developmental history, and the social context (Mortimer, 2010). Importantly, efforts to address selection effects, wherein adolescents who work (and work in varying amounts) differ prior to employment, have increased substantially in the past 15 years. While the jury is still out, at least some of these studies indicate that the problems associated with adolescent employment are partially or wholly due to selection processes.

Neighborhood

Neighborhoods structure adolescents' lives physically and socially; they are the settings in which families live, they are often the basis for school assignment, and they tie adolescents and their families to other organizations (e.g., religious organizations) and opportunities (e.g., jobs for teenagers). Studies of neighborhood effects on adolescents have expanded greatly since the mid-1990s, much of it motivated by a concern with economically disadvantaged neighborhoods and their relation to risk behavior (Sampson et al., 2002). The key issue is whether and how neighborhood characteristics (e.g., rate of poverty in neighborhoods) affect residents above and beyond individual and familial characteristics (e.g., family income).

Residential stability, racial/ethnic heterogeneity, density, and other characteristics are tied to adolescent outcomes in varying ways, though studies of concentrated disadvantage (and advantage) have dominated the field (Sampson et al., 2002). For example, Harding (2003) finds that those growing up in neighborhoods with higher rates of poverty are more likely to drop out of high school, and girls are more likely to become pregnant as a teenager. Looking at neighborhoods from the other side, that of advantage, Ainsworth (2002) shows adolescents' math and reading test scores are higher when the proportion of high status adults (i.e., those with college degrees or working in managerial or professional occupations) in the neighborhood is higher.

The study of neighborhood effects also considers the overlapping context of adolescents' lives, particularly how neighborhoods and parents jointly shape adolescents. In a study of adolescent sexual behavior, Browning et al. (2005) find evidence of both family and neighborhood effects on the timing of first sex. Attachments to family delays onset of sex, and neighborhood poverty accelerates it. But key aspects of parenting and neighborhoods work in conjunction with one another. Neighborhood collective efficacy (a measure capturing social cohesion and the tendency for adults to know each other and each other's children) only delays sexual onset among adolescents who experience low place monitoring by their parents (i.e., being allowed to wander in public places without supervision). The effects of neighborhood and school collective efficacy can also depend on each other. A recent study by Kirk (2009) reports that school collective efficacy reduces the likelihood of suspension, especially when neighborhood collective efficacy is low. In contrast to the compensatory nature of the relationship for school suspension, an accentuating process was observed for likelihood of arrest with low levels of collective efficacy in both the neighborhood and school most problematic.

Harding's (2010) in-depth study of Black and Latino adolescent boys in poor as compared to working class neighborhoods also highlights how neighborhood conditions structure peer networks. Fear of violence, and in particular

violence that is structured as cross-neighborhood rivalries in the inner city, fosters cross-age interactions among adolescent males. Older boys, who have earned status by successfully navigating the dangers, are sources of protection for younger boys, but are also sources of cross-age socialization. Mostly jobless, these older males introduce alternative cultural models to younger males that exist alongside mainstream cultural models in poor neighborhoods. Adolescent boys are thus exposed to conflicting and confusing models providing information about opportunities, risks, and pathways to success in work, school, and relationships.

Adolescents as Actors

Sociologists recognize adolescents as actors in their own lives, navigating and influencing relationships, selecting contexts in which they interact, and making choices with short- and long-term goals in mind. As already noted, adolescents choose the friends that come to influence them. Adolescent employment can also be viewed as instrumental action in which adolescents invest in employment in ways that fit into their longer term plans. A strategy of steady part-time work combined with schooling, for example, appears to facilitate educational attainment in young adulthood, especially for those showing lower educational promise during high school (Mortimer, 2010). At times these social processes are framed as selection problems – something that must be dealt with in order to isolate the effects of other experiences (e.g., friend behavior, hours of work) on adolescents. Yet they are also a critical aspect of the sociological approach and at times become the central question itself.

One area in which this is clearly evident is in the study of peer culture. Adolescents enact, modify, ignore, or resist ideas and pressures from society in creating peer cultures. In her study of masculinity and sexuality, for example, Pascoe (2007) documents how high school students as well as adults and institutional practices such as school rules all work together to construct adolescent masculinity. A key practice teen boys engage in to affirm their own masculine identities is to call other boys 'fags' as insults and participate in other homophobic rituals in school settings. Various unmasculine acts can elicit the name-calling, but the terms hold racialized as well as sexualized meanings. Black boys, who are hypersexualized in the US culture, have much greater freedom to care about their clothing and appearance without risking the label. In fact, clothing is important to status seeking, particularly among poor Blacks. Dancing, too, is associated with being a fag for White boys, but for Black boys it reinforces community membership and being skilled at dancing is again associated with higher status. Black boys, who use the fag epithet less frequently themselves, get in trouble with school personnel more often when they do use it, however. These practices, alongside heterosexual locker-room talk and formal school rituals emphasizing heterosexual norms (e.g., school dances in which sexual and sexist lyrics are featured and school assemblies featuring competence in hypermasculine behaviors), define masculinities in high school.

Adolescents are not passive recipients of parenting either; their behavior and values can affect parents. Hawkins et al. (2007) demonstrate that engaged parenting among nonresident fathers is a response to, rather than a cause of, adolescent well-being. As another example, parent-adolescent value similarity is generated not only through parental socialization of offspring, but also through adolescents' influence on parents. Pinquart and Silbereisen (2004) find that adolescents' values shape their parents' values, especially when parents are more authoritative – that is, they combine high levels of support with monitoring and involve adolescents in discussion and family decision making. Through these and many other examples, sociologists explain how adolescents are key actors in the processes creating the social world around them.

Interdisciplinary and Multidisciplinary Endeavors

Emerging trends in the sociology of adolescence include bringing together insights and research methods from multiple disciplines. Advances in understanding brain functioning, for example, have helped contextualize the higher level of risk behavior of adolescents compared to children and adults (Steinberg, 2008). Two further examples, discussed in detail, illustrate the potential for combining an understanding of the social world of adolescence with that of biology and genetics.

The first example speaks to the gains made in understanding prosocial development when combining traditional social science data with biological data. Fuligni and colleagues (e.g., Fuligni and Telzer, 2013) have been examining the interaction of adolescents' family lives with biological processes in development. Their UCLA Study of Adolescents' Daily Lives collected data during high school using traditional questionnaires and daily intensive reporting of activities and experiences for 2 weeks, along with blood samples at 18 years of age and functional magnetic resonance imaging (fMRI) brain scans a year later during which participants worked through a decision-making task. They find that adolescents who report helping their families more (e.g., caring for siblings, cooking) do report feeling more burdened by family responsibilities, but also report feeling happier. Feeling like a good son or daughter and a good sister or brother, a form of role fulfillment that results from helping behavior, explains this greater happiness. Consistent with these reports, time spent helping was also associated with two biomarkers at 18 years of age (soluble interleukin 6 receptor and C-reactive protein) that are thought to result from chronic stress, but levels of these two biomarkers were lower for adolescents whose family assistance brought them greater role fulfillment.

Furthermore, the fMRI results indicated that the meaning of family helping behavior was associated with neural activity. Brain scans were taken while participants worked through a task involving decisions in which they or their family gained or lost financially. Adolescents who earlier experienced greater role fulfillment through helping the family experienced greater neural activation in regions of the brain associated with reward when they made decisions that involved personal sacrifice for their family's gain compared to when they gained personally. Hispanic adolescents, who tend to place more importance on helping their families, also demonstrated this pattern under the same scenario. In contrast, non-Hispanic Whites showed greater activation of these regions when they experienced financial gain personally. This example demonstrates that

biological response can depend on the social and cultural meaning of behavior, and suggests that health and well-being depend on a complex interaction between both.

The study of gene–environment interactions has been another growth area in the study of adolescence. Genetics may be one of the factors that aids in understanding individual variation in how social conditions shape behavior. The National Longitudinal Study of Adolescent Health (Add Health), which collected DNA data along with survey data, has greatly facilitated the study of gene–environment interactions in adolescence. Using these data, Shanahan et al. (2008) focus on the DRD2 gene that is thought to increase the likelihood of behaviors dysfunctional in school settings. Consistent with this, the study shows the gene is associated with lower rates of college enrollment among boys. Girls, they hypothesize, may be socialized in ways that damp down the expression of these behaviors even when they share the genetic risk. Among boys, high configurations of social capital (i.e., having higher socioeconomic status parents involved in a high quality school) compensated for the genetic risk of DRD2. Moreover, boys with DRD2 risk were most likely to have configurations of social capital associated with the worst college-going rates. Thus, genetic factors are linked to the likelihood of accessing the resources that would help compensate for genetic risk. Studies such as this highlight the social mechanisms involved in the relationship between genes and behavior. Scholars of adolescence will need to continue to leverage theory and data from other disciplines in order to fully understand adolescent development.

This article is a revision of the previous edition article by T.A. Wills, volume 1, pp. 105–112, © 2001, Elsevier Ltd.

Abstract

This article considers adolescent health behavior with a focus on the major contributors to mortality in adolescence and young adulthood. We consider substance use, sexual risk behavior, and violence as well as suicide risk. These various risk behaviors tend to occur together and have similar though not identical predictors. Theoretical approaches to vulnerability or protection for these outcomes include attitudinal models, social influence and social perception models, stress-coping models, and recent dual-process models. This article discusses how risk may derive from contributions of environmental variables, family variables, personality characteristics, life stress, and peer social networks. Directions for future research are considered briefly.

This article considers adolescent health behavior with a focus on the major contributors to mortality in adolescence and young adulthood. We consider substance use, sexual risk behavior, and violence as well as suicide risk. These various risk behaviors tend to occur together and have similar though not identical predictors. Theoretical approaches to vulnerability or protection for these outcomes include attitudinal models, social influence and social perception models, stress-coping models, and recent dual-process models. This article discusses how risk may derive from contributions of environmental variables, family variables, personality characteristics, life stress, and peer social networks. Directions for future research are considered briefly.

Definition of Adolescent Health Behavior

This topic comprises two related areas. One area concerns behaviors that may create risk for immediate threats to health during adolescence (e.g., accidents), the other concerns behaviors that place individuals at increased long-term risk for chronic diseases in adulthood (e.g., cancer). Research on adolescent health behavior aims to determine factors related to increased risk for health-compromising behaviors such as cigarette smoking (i.e., risk factors). Protective factors such as family support operate to decrease risk for these behaviors in general and, in addition, may reduce the impact of risk factors (i.e., buffering effects). This article considers factors related to substance use, sexual behavior, violence, and suicide risk (*see* Health Behaviors).

Intellectual Context

The study of adolescent health behavior arose from epidemiological research during the 1950s and 1960s demonstrating that mortality from chronic disease in adulthood, such as heart attack or cancer, was related to factors such as substance use, dietary patterns, and life stress. Studies on longitudinal tracking of behavioral and physiological risk factors gave recognition to the concept that risk status began to develop before adulthood. This suggested a focus on studying health-related behaviors such as cigarette smoking at younger ages so as to determine whether there was empirical support for early preventive approaches.

In the present article our focus is guided by data on causes of mortality. The United States data for 2010 from the Centers for Disease Control show that for adolescents (persons of 15–24 years of age) and young adults (25–34 years of age) the most common causes of mortality in order of frequency are accidents, homicide, and suicide. Cardiovascular disease and cancer only assume prominence at later ages. Though the relative rates for different causes could vary across countries, these statistics draw attention to the fact that accidents, interpersonal violence, and suicide are the leading causes of mortality during adolescence. It is noteworthy that substance use contributes to all these types of mortality. For example, alcohol use is a factor in the majority of fatalities from auto accidents (Taylor et al., 2010) and toxicology studies show that drug use is implicated in both homicide and suicide (Darke, 2010; Sheehan et al., 2013). Thus, inquiring into factors related to substance use is important for understanding the origins of these outcomes.

The factors that place adolescents at risk for substance use and sexual risk behavior span several domains. While demographic and environmental factors may have a role in risk behavior (Gardner et al., 2010), personality factors that contribute to emotional states such as depression and anger are also implicated in risk for substance use and violence (Colder et al., 2010). Sexual risk behavior (e.g., unprotected intercourse, multiple partners), a factor in HIV infection and other sexually transmitted infections, is related to many of the factors that predict adolescent substance use (Salazar et al., 2009). The article focuses on research relevant to these conditions, noting that drug use and sexual risk behavior tend to occur together and personality variables may contribute to their cooccurrence (Cooper, 2006; Wills and Ainette, 2010).

Dominant Theories and Changes in Emphasis over Time

Early Theoretical Models

Cognitive approaches such as the *health belief model*, developed by Rosenstock and Becker, posit that health behavior is based on a reasoned analysis of the perceived benefits of the

behavior, the costs (health, social, or economic) associated with the behavior, and the perceived barriers to engaging in the behavior (*see* Health Behaviour, Psychosocial Theories of). Though these rational models of health are intuitively plausible, knowledge about health consequences has not eliminated cigarette smoking and measures of health knowledge often do not correlate well with behavior. Attitudinal approaches such as the *theory of reasoned action*, developed by Fishbein and Ajzen, posited that favorable attitudes lead to intentions to perform a given behavior, and intentions are then related to occurrence of the behavior. Empirical studies have provided some support for this model but a number of studies have shown the relation between intentions and behavior to be only moderate, and questions have been raised as to how cultural differences in values can limit the global translation of prevention programs based on Western attitudes toward health (DiClemente et al., 2009).

Subsequent theories include the *problem behavior model*, developed by Richard and Shirley Jessor (see Jessor, 1998). This model construes adolescent substance use as a behavior linked to rejection of conventional societal norms for achievement and behavior. This model proposes that tolerance for deviance is produced by factors such as a poor relationship with parents, alienation from conventional routes to achievement (e.g., academic performance), and affiliation with peers who are engaging in deviant behaviors such as fighting, stealing, and substance use. The problem behavior model predicts that individuals who reject conventional values will rebel through adopting multiple deviant behaviors (e.g., heavy drinking, marijuana use, precocious sexuality). This model was the first to account for the observed intercorrelation of various problem behaviors, and prevention programs typically include an aim to reduce deviance-prone attitudes and affiliation with antisocial peers (Smith et al., 2006). The *social influence model* proposes that many behaviors are acquired through observing and modeling the behavior of influential others, and delineates the role of affiliation with peer smokers or drinkers in facilitating the adoption of these behaviors (Hoffman et al., 2006). This approach has been successful in demonstrating that peer affiliations are a final gateway factor for the effects of other variables (Wills et al., 2011) and this model has provided the rationale in prevention programs for teaching skills for resisting peer pressure.

Changes in Focus over Time

Over the last decade, the range of variables shown to predict substance use has led to statistical models emphasizing how risk or protection arises through an interplay of contributions from individual, environmental, and social factors (Wills and Ainette, 2010). Thus, recent research on adolescent substance use has used multivariate analyses that test multiple domains of predictors. One specific change in focus is the conceptualization of social influence processes. Previously it was assumed that adolescent smoking, for example, was caused by explicit pressure applied by smoking peers to unwilling (or ambivalent) targets. However, current research has demonstrated that adolescents' perceptions about the prevalence of peer smoking and drinking are often biased upward and teens perceive more acceptability of substance use than peers actually endorse (Hoffman et al., 2006). These cognitive aspects of social perception make some individuals more likely to adopt smoking, alcohol use, or sexual risk behavior. This knowledge has been incorporated in prevention programs with components to correct erroneous normative perceptions and focus on negative perceptions of teen substance users (Sussman and Ames, 2008).

Recent research has given more prominence to affective factors, as evidence shows that problem behavior tends to occur among adolescents experiencing higher levels of stress or anger (Sinha, 2008). The observation that characteristics measurable in childhood (e.g., irritability, conscientiousness) predict health-related behavior at later ages has led to theories aimed at understanding how early temperament attributes are related to the development of problems with behavioral and emotional regulation at later ages (Wills and Ainette, 2010). Though relations of different aspects of emotion to risk behavior can be complex (Colder et al., 2010), current theories have drawn out the linkages of emotional distress to patterns of peer affiliations and willingness to use substances if an opportunity presents itself. In addition, recent research has shown that difficulty in controlling emotions and behavior is a risk factor for several types of health behavior (Wills et al., 2013a) and has linked poor emotional regulation to suicide risk during adolescence (O'Connor et al., 2012; Wagner, 2009).

Finally, recent theoretical developments have recognized that two different systems are involved in processing information relevant for health behavior. One system is based on deliberative processing of information, with systematic consideration of risks and benefits; the second approach is based more on judgment heuristics and reactions to images. These two modes of processing – sometimes termed the *reflective* and *reactive* systems – have different properties, the first being slower, more controlled, and requiring cognitive effort, whereas the second is quicker, more impulsive, and more automatic in its operation (Gerrard et al., 2008). These concepts have been incorporated in *dual-process theory*, which posits that the reflective and reactive systems make independent contributions to outcomes, so assessing the tendency to use each of these systems may enable better prediction of health risk behaviors (Wills et al., 2013a).

Emphases in Current Research

This section summarizes current knowledge about variables that are related to adolescent health behaviors. Listing a variable as a predictive factor does not indicate that it is the sole cause or even necessarily a strong cause of a behavior. A given variable may not be a major predictor of a behavior from a statistical standpoint, but a combination of variables can have strong predictive power. Also, buffering effects are common in health behavior. For example, a person with high life stress might show few adverse health outcomes because he/she also had a high level of family support. Thus there is no single magic bullet that can be used to tell who is at high risk and who is not. To predict health behavior with confidence, one has to assess multiple variables and consider the balance between levels of risk factors and protective factors. We emphasize also that

there are intercorrelations among the various risk behaviors and a substantial degree of commonality in their predictors. Separate lists of predictors for substance use, injury and violence, and sexual risk behavior would have considerable overlap (DiClemente et al., 2006; Sussman and Ames, 2008; Salazar et al., 2009; Wills and Ainette, 2010). So in the following section we simply give examples of predictors for each of the behaviors.

Demographic Variables

Substance use among US adolescents varies by gender (males typically showing higher rates by 12th grade), ethnicity (higher rates among Caucasians, lower rates among African-Americans), family structure (higher rates in single-parent families), religiosity (lower rates among persons who attend a religious organization), and parental socioeconomic status, with generally higher rates among adolescents from families with lower income and education (Johnston et al., 2013). Socioeconomic effects however are complex, with different patterns for different indices of substance use (e.g., overall alcohol use versus heavy drinking). It is typically found that effects for demographic variables are mediated through risk and protective factors listed subsequently (e.g., academic involvement). We note that demographic effects observed in the US data could differ across countries, so reference to local data is always warranted.

Environmental Variables

The available data suggest that there is elevated risk for substance use in neighborhoods with lower income and higher crime rates, and where the neighborhood is perceived by residents as dangerous and/or neglected by the local government (Gardner et al., 2010). Noting the existence of a relationship, however, fails to characterize the great variability in effects of environmental variables. For example, a large proportion of persons growing up in poverty areas may go through adolescence showing little or no substance use. This is believed to occur because family processes provide protective effects that can offset the risk potential of the environment (Wills et al., 2013b).

Temperament Dimensions

Temperament dimensions evident from early ages such as attentional orientation, the tendency to focus attention on a task, and positive emotionality, the tendency to laugh and smile frequently, are indicated as protective factors. Indicated as risk factors are activity level, the tendency to move around frequently and become restless when sitting still, and negative emotionality, the tendency to be easily irritated and become intensely upset. It appears that these variables act through affecting the development of generalized self-control ability (Wills and Ainette, 2010). Two other temperament-type constructs have been related to substance use, drunken driving, and sexual behavior in adolescence. Novelty seeking reflects a tendency to need new stimuli and situations frequently and to become bored easily. Sensation seeking is a related construct in which high scorers prefer intense sensations (e.g., loud music) and show a preference for engaging in exciting and dangerous activities (Sussman and Ames, 2008).

Family Relationships

A positive relationship with parents is an important protective factor for several health risk behaviors. High supportiveness is present when adolescents feel that they can talk freely with a parent when they have a problem and that parents will provide emotional support or practical assistance when it is needed. Family support is consistently observed to have buffering effects, reducing the impact of risk factors such as negative life events (Wills et al., 2013b). Family support acts through multiple pathways, associated among adolescents with better self-control, higher academic competence, and less affiliation with deviance-prone peers.

A conflictual relationship with parents, involving disagreements and frequent arguments, is a risk factor for various adolescent problem behaviors. It should be noted that some argumentation between parents and children is normal, as teenagers establish autonomy from their parents and work toward their own identity; but a high level of conflict, in the absence of protective factors, is potentially problematic. Young persons who feel rejected by their parents look for other sources of acceptance and approval and tend to gravitate into groups of deviance-prone peers, which can lead to drug use and risk-taking behavior (Jessor, 1998). A high level of arguments with parents can be a significant risk factor and ameliorating family conflict is an important focus for counseling and prevention programs (Smith et al., 2006).

Self-Control and Dysregulation

Behavioral self-control, also termed planfulness, is measured by attributes involved in planning, organizing, and monitoring behavior and dealing with problems through considering alternatives and making a decision about how to solve the problem. Emotional self-control involves soothability, the ability to calm down when one is excited or upset, together with ability to regulate emotional states such as anger and sadness. Self-control is a protective factor for substance use through helping to promote academic competence and ensuring that problems get resolved rather than accumulating over time and producing high life stress (Wills et al., 2011).

Behavioral dysregulation, also termed impulsivity or disinhibition, is manifested as impatience, impulsiveness, and present orientation – the tendency to be reactive to present situational cues without much thought to the future. Emotional dysregulation can manifest as irritability (a sample item being, "There are a lot of things that annoy me"); affective lability, the tendency to change moods quickly; and rumination, a tendency to dwell for long periods of time on remembered episodes of anger or sadness. Dysregulation is related to lower involvement in school and seems to be a risk factor for bringing on negative life events. In later adolescence, poor regulation is associated with perceiving substance use or sexual behavior as useful for coping with life stress, an important factor in high-risk behavior (Cooper, 2006; Wills et al., 2011). Also, self-control buffers the effect of dysregulation, so an individual's level of poor control is less predictive than the

balance of self-control and dysregulation (Wills and Ainette, 2010).

Aggressiveness and Hostility

Whether aggressiveness derives from temperamental attributes (e.g., irritability), is a facet of behavioral and emotional dysregulation, or is a consequence of adverse social conditions (e.g., school failure) could be argued, but in a sense all these conceptualizations are correct. The empirical fact is that verbal or physical aggressiveness is stable over time from childhood onwards, leads to difficulties with parental socialization and peer social relationships, and is a strong correlate of substance use and other problem behaviors. A predisposition to respond aggressively in interpersonal situations is conducive to injury through violent encounters, making this an important factor in adolescents' injuries as well as injury to others (DiClemente et al., 2006). Overt physical aggression is part of a syndrome that also involves impulsiveness and negative affect, and diagnostic studies show that a substantial proportion of youth with antisocial behavior also have high levels of negative mood. The combination of high levels of aggression and depression is a particular risk factor for both substance abuse and suicide in adolescents. However, clinical-level disorder is not a necessary condition for risk, as simple measures of anger predict substance use in adolescence quite well (Wills et al., 2011).

Academic Involvement or Disengagement

Interest in academics and good performance in school is an important protective factor among adolescents, whereas disengagement from school is a notable risk factor for adolescent substance use and other problem behaviors. Disengagement may be reflected in negative attitudes toward school, low grades, and a history of discipline in school. The effect of academic involvement is independent of characteristics such as socioeconomic status and family structure, though it is related to these to some extent (Wills et al., 2011, 2013a). Low involvement in school could be partly attributable to temperamental restlessness or distractibility, which makes it difficult to adjust to the classroom setting (Wills and Ainette, 2010). Disinterest in getting good grades may also derive from a conflictual family that does not socialize children to work toward long-term goals or a social environment that devalues conventional routes to achievement (Jessor, 1998). Adolescents may have one bad year in school and do better in subsequent years, without adverse effect; but a trajectory of deteriorating academic performance could be predictive of subsequent problems such as substance abuse.

Life Events, Emotional Distress, and Coping Motives

An accumulation of negative life events during the previous year has been implicated in substance use and in suicide risk (Sinha, 2008; Wagner, 2009). The life events may be ones that occur to a family member (e.g., unemployment of a parent) or ones that directly involve the adolescent him/herself (e.g., loss of a friend). High life stress has been shown related to increased affiliation with deviant peers, apparently because experiences of failure and rejection dispose the adolescent to disengage from conventional institutions and spend more time with peers who are themselves frustrated and alienated. Life stress also may prime a need for affect regulation mechanisms to deal with the emotional consequences of stressors, hence it is related to coping motives for substance use, a predictor of substance use problems (Wills et al., 2011).

Negative emotional states including depression and anxiety have been linked to adolescent substance use and other problem behavior (Colder et al., 2010). The source of the negative affect may be from recent negative events, from dispositional characteristics (e.g., neuroticism), and/or from living in an unsafe environment; some current evidence supports each of these perspectives. An individual reporting a high level of depressive affect on a symptom checklist is also likely to endorse beliefs that he/she is an unattractive and unworthy person, that current problems are uncontrollable, and that there is no clear purpose or meaning in their present life. Evidence has linked components of this complex (lack of control, pessimism, and perceived meaninglessness) to adolescent substance use and suicide risk (Wagner, 2009). Note that positive affect (which is not simply the absence of negative affect) is a protective factor for various problem behaviors and has buffering effects, reducing the impact of negative affect on substance use (Colder et al., 2010). Thus it is important to assess the balance of positive and negative affect for an individual.

Persons may engage in a given behavior for different reasons, and the reasons have significant implications for adolescent health behavior. Problematic substance use and sexual behavior are prominent particularly among individuals for whom these behaviors are regarded as an important coping mechanism, perceived as useful for coping with negative affect and reducing stress (Cooper, 2006). Coping (as opposed to social) motives distinguish adolescents who use tobacco and alcohol at relatively low rates from those who use multiple substances at high rates and experience negative consequences because of inappropriate use (Wills et al., 2011). Coping (as opposed to social) motives distinguish adolescents who use multiple substances at high rates and experience negative consequences because of inappropriate use from those who use tobacco or alcohol infrequently or not at all (Wills et al., 2011).

Specific Attitudes and Efficacies

Persons who perceive a problem behavior as relatively accepted in their social circle, and/or perceive they are less vulnerable to harmful consequences of use, are more likely to engage in the behavior. Attitudes do not have to be totally favorable in order to create risk status; for example, perceptions of cigarette smokers tend to be negative in the general adolescent population, but those who have relatively less negative perceptions are more likely to begin smoking (Gerrard et al., 2008). It is likely that some variance is attributable to attitudes about substance use communicated by parents (Wills et al., 2013). Influential peers certainly communicate norms about substance use, which tend to differ from those held by parents, and mass media may also communicate favorable images about substance use and sexual behavior (Wills et al., 2013, 2008). Ongoing studies

conducted among US teenagers have shown that rates of substance use vary inversely with attitudes in the population about the harmful effects of cigarettes or marijuana (Johnston et al., 2013). The source of these trends has not been decisively linked to any specific source, but school-based preventive programs and government-sponsored counteradvertising have been suggested as influential (*see* Health Risk Perception).

Specific efficacies are relevant for averting risk behavior. In the area of sexual behavior and contraceptive use, perceived efficacy for discussing contraceptive use with a partner is an important protective factor (Salazar et al., 2009). There are widely varying attitudes about condom use and differences across persons in the degree to which they feel comfortable in communicating with partners about condom use. Thus studies should always make an attempt to address specific beliefs and attitudes about a health behavior. High resistance efficacy, the belief that one can successfully deal with situations that involve temptation for a behavior (e.g., being offered a cigarette at a party), is consistently noted to be a protective factor. Some data have shown efficacy linked to a good parent–child relationship, to good behavioral self-control, and (inversely) to indices of low self-regard (Wills et al., 2007).

Peer Relationships

Across a large number of studies it has been noted that adolescents who smoke, drink, fight, and/or engage in sexual risk behavior tend to have friends who do likewise (e.g., Hoffman et al., 2006). Thus the frequency and extent of peer use is a major consideration for risk status. For example, many teenagers will end up at times in situations where a friend is using some substance, but when many of a person's friends are smoking and drinking frequently and perhaps feeding a growing cycle of alienated beliefs, then concern would mount. Aspects of the context of peer group membership should be considered. While engagement in peer–group activity is normative and desirable for adolescents, it is when a person has high support from peers and low support from parents that substance use is particularly elevated (Wills et al., 2013b). In addition there may be several types of peer networks in a given school, including groups that are academic or athletically oriented as well as subgroups focused around deviant interests (e.g., substance use); hence the frequency of peer activity may be less important than the types of peers and their associated behaviors (Sussman and Ames, 2008). Responding to peer behavior has been a primary focus in prevention programs, which aim to teach skills for communicating well with peers and responding assertively in situations where an opportunity for a problem behavior arises.

Racial/Ethnic Discrimination

In recent years it has been recognized that racial/ethnic discrimination is a significant factor in poor health status. Studies with adolescents are showing that perceived discrimination is related to cigarette smoking and heavy alcohol use as well as to elevations in emotional distress, and discrimination has been linked to cardiovascular disease and other adverse health outcomes in adulthood (Williams and Mohammed, 2009). Explanations advanced for the effect of discrimination on substance use include feelings of resentment and anger and disengagement from conventional institutions (e.g., school). Current studies are examining how discrimination operates to erode self-control and hence make adolescents more vulnerable to a range of disease conditions (Gibbons et al., 2012). However, buffering factors such as strong family support may help to counteract the adverse effects of racism (Wills et al., 2013b).

Obesity, Dietary Intake, and Physical Exercise

A rising health concern globally has been the substantial increase in the prevalence of overweight and obese children and adolescents (Spruijt-Metz, 2011). This health problem has arisen in the United States as well as European countries (Janssen et al., 2005). The public health issues linked to adolescent obesity include adolescent health problems such as type II diabetes and increased risk for cardiovascular disease and some types of cancer in adulthood. Stigmatization and harassment of overweight youth also have significant negative consequences in adolescence (Bucchianeri et al., 2013). There is no single cause for the increased prevalence of obesity, although dietary intake is quite relevant. Dietary patterns have changed substantially in the past few decades. There has been a rise in consumption of soft drinks and candy and a decline of fruits and vegetables in adolescents' diets in many countries, and these have been implicated in the increase in childhood and adolescent obesity (Spruijt-Metz, 2011). In addition to educating children and adults about the causes of obesity, goals of current prevention programs include changing shopping environments so as to increase access to affordable healthy foods, while policy initiatives discourage consumption of sugary drinks and aggressive marketing of children's meals that are high in calories and fat (Spruijt-Metz, 2011).

In the past few decades physical activity patterns in adolescents have also changed. There has been an increase in time spent watching television and using computers, and a decrease in opportunities for physical activity in schools and communities (Iannotti and Wang, 2013). The patterns of physical activity also vary across countries (Janssen et al., 2005). Low physical activity in adolescents is linked concurrently to overweight and lower cognitive performance, and on a long-term basis it has been connected to parameters of the metabolic syndrome, which creates risk for cardiovascular disease (Spruijt-Metz, 2011). While screen-based sedentary behavior (particularly television viewing) has been linked to subsequent adiposity, low physical activity has also been related to adverse psychological outcomes including lower quality of life and quality of family relationships (Iannotti and Wang, 2013). It is important that national governments and international agencies promote physical exercise, provide neighborhood environments that make physical activity easy and safe, and educate the public about the interrelation of exercise, diet, and weight. Furthermore, more research is needed on predictors of high body mass index and low physical activity, in order to understand the factors associated with them.

Future Directions

This article has emphasized that meaningful risk is not predictable from knowledge about a single variable; rather it is the

number of risk factors and their balance with protective factors that is most informative. The concept that health behavior is related to variables at several levels of analysis (environmental variables, personality variables, family variables, and social variables) has been emphasized, and the article has discussed mediating pathways through which these variables operate to produce favorable versus unfavorable health outcomes.

Several future developments can be anticipated in this area. One is increasing use of theories that delineate how different domains of variables are related to problem behavior. For example, epigenetic models suggest how simple temperament characteristics are related over time to patterns of family interaction, coping, and social relationships, which are proximal factors for adolescent substance use and other behaviors (Wills and Ainette, 2010). Research of this type will be increasingly interdisciplinary, involving investigators with expertise in behavior genetics, developmental and social psychology, as well as anthropology and neurobiology.

Another development is the increasing integration of genetic research with psychosocial research. It has been known for some time that parameters relevant for cardiovascular disease (e.g., blood pressure and obesity) have a substantial heritable component, and recent research has shown substantial genetic contributions for liability to cigarette smoking and alcohol abuse/dependence (Korhonen et al., 2012). Although health-related variables have consistently been shown related to genetic characteristics, there is less understanding of the physiological pathways involved. Current investigations are studying genes coding for receptors for neurotransmitters that have been linked to vulnerability to substance abuse and suicide and identifying physiological and behavioral pathways for the effects of genetic variation.

Finally, life span research has indicated that simple temperament characteristics measured at early ages predict health-related outcomes over considerable periods of time (Wills and Ainette, 2010). Such research suggests investigations into whether early temperament characteristics are related directly to physiological pathways from the hypothalamic–pituitary axis, operating to dysregulate metabolic systems so as to create risk for cardiovascular disease and diabetes. Behavioral pathways are also possible in observed longevity effects through liability for smoking or accident-proneness. Integrative research is suggested, using concepts from physiology and behavioral psychology to understand the role of psychosocial processes in premature mortality.

Adolescent Sexual Risk

Christopher Browning and Jenny C Malave, The Ohio State University, Columbus, OH, USA

Abstract

This article reviews recent trends and theoretical approaches to understanding variation in exposure to sexual risks during adolescence. Sexual risks can be understood as capturing sexual behaviors and exposures that increase the likelihood of teenage pregnancy, sexually transmitted disease, and sexual violence. We present estimates of the distribution of adolescent sexual risk over time and by key demographic correlates such as age, gender, and race/ethnicity. We then consider research on the etiology of sexual risk, including neuropsychological, social network, and neighborhood/ecological factors. Discussion of new directions for research on sexual risk highlights the considerable potential of multilevel, integrated approaches.

Introduction

Research on 'normative' sexual development during adolescence can be traced back to early-twentieth-century psychoanalytic approaches and the tradition of ontogenic theorizing that followed (Dannefer, 1984). The latter half of the century saw both the apogee of psychoanalytic and related approaches to sexual development and their subsequent decline in the face of fundamental challenges to the notion that 'normal' (and, by implication, deviant) sexual development could be an organizing category for research. Mounting evidence of considerable diversity in sexual behavior, attitudes, and orientation during adolescence led to interest in documenting the complex nature of emerging sexuality. Alongside these debates, the latter half of the twentieth century also saw the increasing prevalence of sexual activity during adolescence and rising sexually related risks such as teen pregnancy, sexual violence, and sexually transmitted infections (including HIV/AIDS). Consensus on the need to understand the etiology of exposure to sexual risks during adolescence has fueled a substantial research literature.

This article emphasizes work on the patterns and origins of adolescent sexual risk. Specifically, the focus of this article will be on examining the various approaches currently utilized within the field of research on adolescent sexual risk, highlighting the need for integrated orientations that incorporate not only individual-level propensities toward risk behavior, but the social network and broader ecological and neighborhood factors that influence risk as well.

We begin with a brief overview of trends in the distribution of sexual risks across time and populations. We then review approaches to the etiology of sexual risk, focusing on three general themes: (1) psychological, biological, and other individual-level predisposing factors; (2) social network contexts; and (3) ecological (neighborhood and institutional) factors that shape sexual risks. In the following sections particular attention will be given to examining the social context in which people are embedded. This article concludes with a brief overview of the strengths of an integrated approach in which individual, network, and ecological factors are incorporated.

Background

The concept of *sexual risk* includes both sexual risk-taking behavior as well as exposure to risks such as sexual violence. Sexual risk taking can include a myriad of behaviors, most commonly defined in terms of inconsistent use of birth control or contraceptives, multiple or concurrent partners, as well as early initiation into sex. These behaviors can lead to a number of negative health outcomes, especially among adolescents. They have been found to increase exposure to sexually transmitted diseases (STDs) (including AIDS/HIV), reduce mental health, and have implications for early childbearing, which can result in uncertain outcomes for both mother and child (Meier, 2003).

Adolescent Sexual Behavior and Risk: Trends and Key Demographic Correlates

We begin with an overview of trends and key demographic correlates of sexual behavior and risk taking. Although reliable data on adolescent sexual behavior have only been available in recent decades, evidence suggests significant changes over time in adolescent sexual risk. Data on the demographic correlates of sexual risk point to the fundamental organizing role of age and gender in the distribution of sexual behavior and sexual risk and demonstrate the unequal distribution of sexual risks across categories such as race and socioeconomic status.

Historical Trends

Self-reports of sexual behavior indicate that sexual activity and teenage pregnancy increased significantly during the 1960s and 1970s (Finer, 2007). These dramatic increases have ebbed in recent years however. The National Survey of Family Growth (NSFG) reports that the percent of unmarried teens between the ages of 15–19 years that have had sexual intercourse has decreased since 1988 for both males and females. Teen pregnancy reached a high point in 1990, but has decreased by approximately 44% since that time. The same is true for birth rates and abortion rates. More recently, between 2008 and 2012, trends have indicated a decrease in abortion and birth rates for teens ages between 15 and 19 years. The 2010 NSFG

finds that the use of contraceptives (including dual use methods, e.g., condoms and hormonal) has increased for both males and females and is likely contributing to the declining rates of teen pregnancy and abortions.

Demographic Correlates

Age is one of the strongest predictors of sexual behavior and risk taking. The probability of sexual onset rises dramatically from early to mid-adolescence, such that between the ages of 15 and 16 years, approximately 30% of youth have experienced sexual intercourse (Finer and Philbin, 2013). On average, males and females experience the first intercourse at the age of 17.1 years (Martinez et al., 2006). Adolescents who engage in sexual activity at younger ages are less likely to use contraceptives, more likely to experience diminished mental health, and more likely to acquire higher numbers of sexual partners throughout the life course (Martinez et al., 2011; Meier, 2003). Additionally, younger teens are more likely to have their first sexual experience with someone with whom they did not have a relationship (Martinez et al., 2011).

The NSFG also shows important differences and similarities in sexual behavior by gender. The percentage of males aged 15–17 years who are sexually active has decreased more rapidly in the past 20 years than for similarly aged females. In 1988, 60% of males in this age group had engaged in sex, as opposed to 42% in 2006–10. Comparatively, female rates have dropped from 51% to 43% over the same period. Extant evidence also points to marked differences across racial/ethnic groups. For example, 25.1% of Hispanic women aged 15–17 years have engaged in sex, as opposed to 30.4% of non-Hispanic white females and 40.8% of non-Hispanic black females (Chandra et al., 2005). Comparatively, 42.6% of Hispanic males, 25% of non-Hispanic white males, and 51.6% of non-Hispanic black males have had sexual intercourse by age 15–17 years (Martinez et al., 2006).

Teen pregnancies exhibit some of the largest discrepancies by race and ethnicity. Among teenagers aged 15–17 years, non-Hispanic whites experienced pregnancy at a rate of 21.6/1000 as compared to 72.8/1000 for non-Hispanic blacks and 69.7/1000 for Hispanics in 2008 (Chandra et al., 2012). African-American youth and young adults are at a higher risk of engaging in sexual activity that will increase the chance of receiving or transmitting an STD than any other racial group (Chandra et al., 2012). A substantially larger percentage of non-Hispanic black men and women aged 15–24 years report having five or more partners within a given year in comparison to non-Hispanic whites and Hispanics (Chandra et al., 2012); 9.5% of non-Hispanic black men and 2.5% of non-Hispanic black women report having had more than five sexual partners in the past year compared to 3.1% of non-Hispanic white males, 3.8% of Hispanic males, 1.6% of non-Hispanic white females, and 1.4% of Hispanic females. Non-Hispanic black women within this age bracket were more likely to seek treatment for an STD than other group: 11% sought treatment compared to 3.8% of Hispanic women and 4.6% of non-Hispanic white women (Chandra et al., 2012). Similarly, research has found that consistent use of condoms appears to be lower for minority adolescents than white adolescents (Brown et al., 1992). Explanations for the disparities in sexual risk by race/ethnicity are varied, but an emerging body of evidence points to the role of challenges in the social environments minority groups face. Below, we review a range of explanations for variation in sexual risk. Although we focus primarily on the social context of adolescent sexual risk, we begin with a brief review of emerging biological and psychological research.

Psychological and Biological Factors

Adolescent predispositions to engage in risky sexual behavior are shaped by a host of psychological and biological factors. The complexity of psychological and biological approaches precludes adequate review here; however, we briefly consider some of the promise and potential challenges associated with research on the neuropsychology of risk. A neuropsychological approach emphasizes the role of variability in the development of brain structure and function in shaping individual-level approaches to risk behavior. Neuropsychological research demonstrates the relevance of temperamental, behavioral, and cognitive processes in predicting participation in risky behavior, including risky sexual activity, during adolescence and young adulthood (Ramrakha et al., 2007). Continuity in the expression of neuropsychological deficits across phases of the life course suggests that a small, largely male subgroup may be at particularly high risk for participating in a range of risky sexual behaviors during adolescence and beyond (Moffitt, 1993).

Neuropsychological explanations for the association between age and participation in risky behavior within adolescence have also been offered with implications for understanding the age distribution of sexual risk. Social neuroscience approaches to adolescent risk, for instance, emphasize the role of dramatic changes taking place within the developing adolescent brain, beginning around the time of puberty. Processes occurring in the prefrontal cortex during adolescence influence reward-seeking particularly when in the presence of peers, resulting in diminished self-regulation. In turn, ongoing development of brain structure and function throughout adolescence eventually results in improved self-regulatory capacity and declining incidence of risky behavior (Robbins and Bryan, 2004). Early onset of puberty has also been linked with earlier occurrence of risky sexual activity (Belsky et al., 2010); changes in brain structure and function may partially account for this link to the extent that the association between pubertal onset and risky sexual activity is explained by biological development (Doremus-Fitzwater et al., 2010).

Neuropsychological predictors of adolescent sexual risk have been the subject of increasing scientific inquiry in recent years as technologies for the assessment of brain structure and functional processes (MRI, fMRI) become more widely available. Although a promising avenue of research, neuropsychological development must be understood as embedded in a larger social context that contributes to both brain structure and function while also constituting the environment in which resulting risk predispositions are manifest.

For instance, early-childhood adversity in the form of exposure to stressors, such as violence and child abuse, may have significant implications for the development of the

prefrontal cortex (Cicchetti, 2002). Traumatic experiences like abuse, in turn, have been linked with the occurrence of risky sexual behavior in adolescence. For example, Wyatt et al. (2002) found that abuse was correlated with more risky sexual behavior and increased risk of HIV across all races and ethnicities. Like low birth weight, however, exposure to early-childhood adversity is structured by a host of economic, demographic, and geographic factors. Thus, increasing evidence of the impact of early-childhood adversity on neurobiological and psychological processes highlights the importance of understanding the social contexts that influence both neurodevelopment as well as other mechanisms that independently contribute to adolescent outcomes. It is these latter processes to which we now turn.

Social Context: Network Factors

A long tradition of research in the social sciences highlights the role of relationships and larger patterns of social ties – captured here by the concept of a *social network* – in organizing the emergence and expression of adolescent sexuality. Despite a considerable literature examining social network influences on adolescent outcomes, the definition of what constitutes a network remains ambiguous. At the individual level, we employ the term 'social network' to encompass the set of relationships maintained by a given person, including intimate relationships as well as more distal social ties and acquaintances. In considering adolescent sexuality, most attention has been paid to the effect of friendship groups or peers, familial networks, and romantic relationships. These ties are characterized by the ability to exert significant influence on the behavior of adolescents.

A network approach to studying adolescent sexual risk can be conceptualized via multiple pathways of influence. First, behavior is shaped by rewards and sanctions conferred through network associates. Friends and family are conduits through which powerful social incentives and disincentives are transmitted to adolescents. Individuals learn which behaviors yield rewards and which result in sanctions – such as social exclusion from the network – through responses to their own behavior and observation of responses to the behavior of key network associates. Second, sexual behavior is shaped by social support – particularly emotional and informational support – that an individual receives from network associates. Lastly, sexual risk behavior is dependent on the availability of social opportunities that facilitate the occurrence of risky behaviors.

Rewards and Sanctions

Vicarious Rewards and Sanctions

Socialization plays a key role in the acquisition of expectations regarding appropriate sexual development and behavior. Behavioral models and sexual norms shape the likelihood of engaging in risk-taking behaviors. In instances where rewards and sanctions are not experienced directly, adolescents perceive what acceptable behavior entails through the behavior of network associates and the subsequent consequence of these behaviors. Reward and sanction processes are especially important to consider during adolescence, as individual participation in sexual behavior is typically only emerging. Simultaneously, the sexual behavior of others in the social environment is highly salient. Social incentives and disincentives to engage in particular types of behavior may vary dramatically by network context – friends and parents, for instance, may model behaviors quite differently. These relationships also vary in dyadic characteristics, such as frequency of time spent together and emotional closeness, as well as embeddedness in larger tie structures, with implications for patterns of influence.

Friendship holds particular importance during adolescence, as the need for social inclusion rises (Berndt, 1982). During this period, adolescents increase the amount of time they socialize with similarly aged peers and tend to distance themselves from parents (Larson and Richards, 1991). Adolescents who find themselves in high-risk networks are increasingly likely to engage in negative health behaviors in order to 'fit in.' For example, an individual is more likely to begin to have sex if there is a high rate of sexual initiation among his/her peer group (Teitler and Weiss, 2000). In general, friends' engagement in sexual activities shapes normative behavior in the peer group, a potentially powerful source of influence during adolescence (Fletcher, 2007).

Low-risk behavior may also be modeled by peers. Studies have shown that perceptions of peer attitudes are especially important to adolescents. Adolescents who perceive that friends hold less favorable views about teen sexual behavior are more likely to delay sexual initiation (Santelli et al., 2004). Perceiving that peers are using contraceptives may encourage individuals to do so as well and has been shown to decrease participation in other high-risk sexual behaviors (DiClemente, 1991; Fisher et al., 1992). Having friends who practice safe sex increases the likelihood that an individual will use similar methods (Berenson et al., 2006).

Similarly, adolescents are also affected by the norms, values, and behaviors of parents. Parents who model more risky behavior are more likely to have children who also engage in sexual risk. Teenagers are more likely to become pregnant if they were born to a teen mother and are more likely to have sex at earlier ages (East et al., 1993). Additionally, low-socioeconomic-status households may consider pregnancy to be acceptable at a younger age, as many markers of adulthood, such as education, are not accessible (Soller and Haynie, 2013; Bettie, 2002). However, parents and other network members also influence sexual risk through *direct* rewards and sanctions.

Direct Rewards and Sanctions

Adolescents experience social control via peers, parents, and significant others. Sexual expression may result in increased popularity, heightened sense of prestige, or alternatively, may be met by shaming, name-calling, or loss of status. Just as acceptable sexual behavior varies widely between school-aged boys and girls (Pascoe, 2007), rewards and sanctions are also organized by gender. Young men are encouraged to express a hypersexual self through bravado, bragging, early sexual experience, and multiple partnering, while young women are typically discouraged from similar behavior (although influences from romantic partners will often counter conventional

sexual expectations for girls) (Muehlenhard, 1988). Participation in sexual activity may increase the popularity or prestige of a given boy among his peers, while girls who act similarly are commonly labeled 'sluts' or 'whores' by boys and girls alike, creating a sexual double standard for adolescents (Aubrey, 2004).

Encouragement from parental networks may not reflect the same values as school-age peer networks. Typically, groups that encourage prosocial norms, like parents, encourage youth to make less risky sexual decisions, while groups like peers and friends encourage more risky behavior. Parents are unique with respect to their ability to enforce sanctions against a child. Parents enforce social control by expressing disapproval of their child's participation in risky behaviors (Dittus and Jaccard, 2000). Subsequent behavioral changes may be explained by a child's unwillingness to jeopardize close relational ties with his/her parents. Children may also perceive that certain behaviors will be rewarded by parents through mechanisms like respect, trust, or praise, which may heighten engagement in or desistence from a particular behavior. Children who feel that they matter to their parents are more likely to avoid engaging in risk-taking behavior than children who lack similar bonds (Elliott, 2010).

For many, adolescence represents the first step into adultlike romantic relationships. Romantic relationships likely represent the first sexual experience that young people will encounter and are therefore categorized by varying degrees of uncertainty. Rewards and sanctions are particularly salient within this setting, as wrong moves may endanger the relationship status. Young women who are dating older men are more likely to engage in high-risk sexual activity, as they lack relative power within the relationship (Males, 1998). As a result, young women with older partners are inhibited in their ability to successfully negotiate sexual interactions (Holland et al., 1992).

Condom negotiation is particularly difficult for young women. Girls commonly cite fear of being rejected by partners as a reason for not discussing birth control (Wingood and DiClemente, 1998). Moreover, many women report that having conversations with partners about safe sex implies distrust in the partner, which can have future consequences (Wingood and DiClemente, 1998). Low self-esteem has also been linked to lack of dialogue between sexual partners with respect to contraception (Sterk et al., 2005; Salazar et al., 2005). Consequently, gender remains a significant predictor of consistent use of contraceptives among adolescents (Ford et al., 2001).

Social Support

Adolescent sexual risk behavior can also be understood as a by-product of social support experienced within an individual's personal social network. A social support framework for the etiology of sexual risk focuses attention on behavioral responses to environmental stressors and the potential moderating influence of social resources. For instance, borrowing from Lazarus and Folkman (1984), one of the ways in which to understand sexual risk taking is as a coping mechanism for dealing with stress. Past studies have linked having multiple partners in a given month to self-reports of having sex to relieve tension (McKusick et al., 1985). Strain can be reduced through the introduction of positive relations that confer social support, specifically emotional and informational support, for turning negative strain into positive outcomes and reducing participation in high-risk sexual behaviors (Folkman et al., 1992).

Emotional Social Support

Emotional support can act as a protective factor that interacts with risk factors to reduce the likelihood of negative health outcomes among adolescents. Social support has been shown to help ameliorate stress caused by poverty (Taylor, 2010), alcohol consumption (Bacharach et al., 2010), and a range of other factors. Parents play a particularly important role in the emotional well-being of adolescents. One study links stronger parental support to lower sexual risk outcomes: Adolescents with stronger mother–child relationships were more likely to delay sexual initiation than those who had weaker bonds to parents (Dittus and Jaccard, 2000). Other studies offer evidence that this relationship is contingent on gender and race: Girls have been found to experience the protective effect of parental support more than adolescent boys (Rose et al., 2005), while white females have been found to experience protective effects of emotional relationships more so than minority females (Miller et al., 1999).

Friends can also play a strong role in providing emotional support during adolescence. Fallon (2010) found that teens were more likely to access emergency contraception if friends accompanied them to the clinic. Friends were found to mitigate much of the social stigma surrounding the use of the morning-after pill by offering emotional support through accompanying their friends to the location. Though research on emotional support within social relations is not conclusive, these studies offer important avenues for exploration. More research is needed to tease out the protective effects of emotional support with respect to sexual risk behavior.

Informational Social Support

Not surprisingly, adolescent sexual risk is also influenced by the informational support an individual receives from their social network. This is particularly true when thinking about how adolescents learn about contraceptives and where to access them. The effect of parent–adolescent communication has yielded mixed results in extant research. While studies show that open communication with parents leads to lower initiation into sex and increased use of contraceptives (Schalet, 2011), other studies have found no significant findings between parental communication and sexual initiation (Jaccard and Dittus, 1993). Studies have shown that many parents fail to have conversations about sex with their children and there is often discordance between adults and adolescence regarding what was discussed (Newcomer and Udry, 1985). In some cases, studies have revealed that having a conversation about birth control may actually increase the odds of an adolescent having sex, albeit protected sex, because they perceive there is parental approval (Jaccard et al., 2000). Others find that children who do have open conversations with

parents have been found to wait longer to initiate sex and to more consistently use contraceptives in a cross-national context (Schalet, 2011).

At the same time, however, social networks can maintain or propagate beliefs that are inaccurate or based on misinformation. Yee and Simon (2010) found that individuals were more likely to trust the anecdotal evidence provided by friends and family than the information provided by a physician. Women were found to reject an effective form of birth control because of the negative experience of a member of their social network, which may ultimately increase exposure to sexual risk (Yee and Simon, 2010). Additionally, parental communications regarding birth control are often found to be inaccurate. Parents who lack proper knowledge about birth control and then transmit this information to their children increase the chances of their adolescent engaging in risky sexual behavior (Jaccard et al., 1999).

Opportunities

Sexual risk behavior is reliant on opportunities that are either created or restricted within social networks. Typically, adolescents who experience early pubertal debut are more likely to engage in higher-risk behavior than later-developing individuals. Pubertal development is linked to social consequences, such as the composition of peer networks, with implications for sexual risk behaviors. Haynie (2003) found that girls who matured at younger ages were more likely to start spending time with older peer groups, especially men, which increased exposure to minor and serious delinquency, encouraged the use of controlled substances, and increased exposure to sexual risks.

Parents may limit exposure to opportunities by restricting access to certain networks like friends or older peers, limiting the amount of time children spend participating in unstructured activities, and supervising the actions of their children. Supervision has been linked to the reduction of delinquency and other problem behaviors (Loeber and Stouthamer-Loeber, 1986). Cohen and Felson (1979) classically posit that deviance occurs only when there is a motivated actor, a suitable object of action, and lack of capable guardianship. If any of the three is missing, action cannot be taken. In this view, the absence of available partners and the presence of guardianship constrain the occurrence of (dyadic) sexual risk behavior.

Many studies have looked at the effect of parental monitoring and have largely found that lack of supervision is linked to increased sexual risk taking. Children who have lower supervision and more unstructured free time are more likely to have earlier sexual initiation (Longmore et al., 2001), multiple sexual partners (Benda, 2002), higher occurrences of risky sexual activity (Huebner and Howell, 2003), and increased frequency of sexual activity (Benda, 2002). Studies have found that having lower levels of supervision around opposite-sex peers is significantly associated with earlier initiation into sex and having ever had sex for adolescents (DiIorio et al., 2004; Perkins et al., 1998).

Adolescents from single-family households are more likely to engage in sexual risk than those living in dual-parent households in part because of lack of supervision (Newcomer and Udry, 1987). Additionally, single-family households are more likely to be of lower socioeconomic status, which may mean the parental figure is working outside of the home. These families may also lack the resources to enroll their child in extracurricular activities or sports, where their child would be monitored by other adults.

Supervision may also be enacted within peer groups with particular norms and values. Specifically, religious groups are likely to hold norms regarding abstinence until marriage. Individuals who are active within church are increasingly constrained by the moral code of the church and are more likely to delay sexual initiation in order to avoid public shaming (Thornton and Camburn, 1989). Religious peers have been found to reduce opportunities in which a person may break their religious commitments by limiting alone time with peers of the opposite sex (Adamczyk and Felson, 2006).

Ecological Factors

Just as adolescents are embedded in networks of social ties, they also spend time in nonhome routine activity locations such as school, places of worship, and neighborhood public spaces. These extraresidential contexts shape adolescent day-to-day experiences and provide the settings in which network interactions are instantiated. This section reviews the expanding literature on the role of ecological contexts in shaping adolescent sexual risk taking.

Neighborhood

Classic perspectives on the role of neighborhoods in shaping adolescent behavior focus on the influence of structural factors such as poverty, residential instability, and race/ethnic heterogeneity in complicating reinforcement of shared community behavioral norms, including those surrounding sexuality (Browning et al., 2005). Indeed, recent literature has pointed to a number of structural features of urban communities in conceptualizing the impact of neighborhood context on adolescent sexual behavior. Growing evidence suggests that neighborhood socioeconomic disadvantage is associated with early sexual debut and related outcomes, such as teenage pregnancy, after individual and family background characteristics are accounted for (Baumer and South, 2001; Browning et al., 2004).

In addition to participation in risky sexual behavior, an expanding literature links communities that have higher levels of residential mobility and economic disadvantage with increased occurrence of sexual assault (Mustaine et al., 2014). For example, Miller (2008) found that within a disadvantaged urban community, sexual assault was common and interventions were unlikely even when the event happened in a public place. This was in part attributed to fear of the criminal justice system and lack of social power among the female residents of the community. Residents were additionally constrained by feelings of powerlessness to change the situation. Thus, sexual victimization often went unreported.

Structurally disadvantaged communities are characterized by compromised social climates along a number of dimensions. Among the most important social processes linked with

structural disadvantage is collective efficacy – or the level of mutual trust, solidarity, and shared values among community residents and associated expectations for prosocial action. While collective efficacy has traditionally been linked to reducing crime-related behavior through informal social control, it has increasingly been utilized as a concept through which to understand community-level variations in a range of risky behaviors, including sexual risk. Shared behavioral expectations at the neighborhood level may lead to collective socialization patterns that limit problem behaviors generally – even those that largely occur in private settings. Browning et al. (2005) found that collective efficacy was negatively associated with early onset of sexual intercourse among urban adolescents. However, this effect was only observed for youth who spent significant amounts of unsupervised time in the neighborhood, suggesting that levels of exposure to neighborhood environments vary across youth and may shape the extent of community influence on behavior. Similarly, evidence suggests that collective efficacy is protective against acquisition of multiple sexual partners during adolescence (Browning et al., 2008).

Other social characteristics more typically associated with disadvantaged neighborhoods have been linked to increases in sexual risk taking among adolescents. Neighborhoods characterized by an absence of recreational options for community members, limited safe environments for socializing with friends and romantic partners, and ineffective parental monitoring have been found to be correlated with increased sexual activity among younger community members (Akers et al., 2011).

Additional evidence suggests that structural disadvantage is associated with access to health-related services that could lower likelihoods of engaging in risky behavior. Neighborhoods with high levels of gang-related violence can negatively impact a resident's ability to access health services (Fleisher, 1998). Early pregnancy may also be considered more normative in a socially disadvantaged neighborhood where pregnancy signals a transition into adulthood for young women (Bettie, 2002).

Institutions

In addition to considering the neighborhood as a residential area, it is important to also consider the institutions embedded within a given space. Institutions, like schools and churches, provide important supervision and socialization contexts. According to De Lamater (1981), social institutions are able to control individual behavior in the following three ways: (1) they define a set of assumptions and norms that define acceptable behavior, (2) those occupying institutional roles will reinforce standards via informal control, and (3) institutions will employ sanctioning systems when norms are violated. Thus, individuals within the institution learn social norms, fear the possible sanctions, and are controlled by the policing of members. Additionally, institutions are able to constrain people in a systematic way so that the ability to engage in or desist from certain patterns is fundamentally altered.

Schools provide an institutional context that may independently influence adolescent outcomes. Some of the most consistent findings within the sexual health literature have been on the positive effect of sexual education. For instance, teens who have had comprehensive sexual education are more likely to effectively utilize birth control than those who were taught abstinence-only education (Kirby et al., 2007). Conversely, with few exceptions (Jemmott et al., 2010), research has suggested that abstinence-only education does not reduce the likelihood of an adolescent engaging in sex; rather, some evidence suggests that it reduces the likelihood of an adolescent knowing how to protect themselves, thus increasing the risk of unwanted pregnancy and STDs (Bearman and Bruckner, 2005).

Participation in religious institutions may also be an important source of influence on adolescent sexual behavior. Most active religions in the contemporary US provide clear dicta against engaging in sexual intercourse prior to marriage. Although the practical emphasis on discouraging sexual behavior among adolescents is more pronounced in certain religious contexts (e.g., Fundamentalist Christian), involvement in religious institutions would typically expose youth to values discouraging sexual activity. Moreover, religious institutions also incorporate youth into activities and social networks that provide other sources of informal social control such as supervised youth groups as well as friendships with youth whose parents are more likely to know one another and share information relevant for controlling behaviors that place youth at risk.

Indeed, some evidence suggests that participation in religious institutions reduces the likelihood of exposure to sexual risk. McCree et al. (2003) found that religion had a negative relationship with risky sexual behavior for African-American females specifically, whereas Bearman and Bruckner (2001) found that religiosity had a negative relationship with the onset of first intercourse among all races other than African-Americans. The effect of religion is stronger for those who actively participate in church or weekly services (Meier, 2003). On the other hand, religious organizations historically focus on abstinence-only teachings. As a result, adolescents who are lacking sexual education at church, home, and school may be unaware of safe sex practices. Recent research looking at the relationship between religion and risky sexual activity has found that religious adolescents who are currently sexually active are less likely to consistently use condoms (Zaleski and Schiaffino, 2000; Bearman and Bruckner, 2005).

Conclusion

The purpose of this article is to synthesize the current literature surrounding adolescent sexual risk-taking behavior. We provide an overview of important etiological factors at the psychological and biological level while paying particular attention to the specific influences of social networks and ecological factors. Past research has largely focused on these explanatory measures as independent of one another, but in fact, these factors may be usefully seen as interacting. Individuals with predispositions to engage in sexual risks are simultaneously embedded in variably influential social networks and ecological contexts. We suggest that future research would benefit from the integration of individual, network, and ecological factors that shape adolescent sexual trajectories.

In moving forward with interdisciplinary and multilevel investigation of sexual risk-taking behavior, researchers should be aware of some of the challenges facing these approaches. First, boundary specification issues plague social network and neighborhood studies alike (Laumann et al., 1989). Determining who is included as part of the network and to what extent certain spaces comprise a given neighborhood are theoretically and empirically thorny problems. Second, future research should consider how to improve data collection efforts. Social network analysis requires relational data, or data containing reference to the relationship among units. Neighborhood analysis requires, at a minimum, information on residential location. Ideally, information on the locations of daily activities should be included as well. Such data is difficult to collect, but will likely yield important findings on the nature of contextual influences on adolescent sexual risk. More generally, new insight into adolescent sexual risk behavior is most likely to come from the intersection of disciplines and substantive domains; thus, future research on this topic should undertake more comprehensive efforts to capture multiple, etiologically relevant domains of influence on human development.

Abstract

Adoption refers to the reassignment or redistribution of parental rights, responsibilities, and practices with respect to a particular child. Adoptions may be informal or formal, private or public, domestic or international, between strangers or kin, transracial or racially 'matching,' and adhering to local norms or 'irregular.' Data on adoptions is difficult to obtain, because these different kinds of adoptions may be recorded differently or not at all. After reviewing this state of affairs, this article challenges the widely circulated narrative that adoption happens because of infertility and changes in supply of children, and explores the relationship between adoption and culture.

Definitions of Adoption

Adoption can be broadly defined as the reassignment or redistribution of parental rights, responsibilities, and practices with respect to a particular child. Scholars and policymakers distinguish between several different kinds of adoption: informal and formal, private and public, and domestic and international. Cross-cutting these categorical distinctions are three other characteristics that are considered salient: whether the adoption is between strangers or kin, whether it is perceived as transracial or racially 'matching,' and whether it adheres to local norms or is 'irregular.'

Formal/Informal

The distinction between informal and formal adoption refers to whether a government is involved in overseeing the transfer of a child. Informal adoption is practiced worldwide and is extremely common. In many parts of the world it is far from unusual for children to spend part or all of their childhoods living with people who are not their biological parents. Anthropological research has found that in places ranging from West Africa to Oceania to Latin America, children may be transferred from one adult to another without the stamp of governmental authority. By contrast, formal adoption is accomplished through courts or government offices. It may also be referred to as legal adoption, although this is not to imply that informal adoption is necessarily illegal or harmful.

Plenary/Simple

Formal adoptions may be plenary, a legal term meaning that they permanently sever a child from his or her family of origin and make him or her officially a child of the new parent or parents in all possible ways (in particular referring to inheritance potential, last name(s), and legal rights). The Hague Convention, which governs international adoptions for all countries that have signed on to it, requires that adoptions conducted under its auspices be plenary (article 2.2). The alternative is that adoptions can be 'simple,' a legal designation meaning that only some parental rights are transferred and a child may still maintain some legal ties to the natal family.

Public/Private

Formal adoptions may be either public or private. Public adoptions refer to adoptions of children who have been declared to be the responsibility of the state. As such, they transfer the responsibility of care from the state to a private family, benefiting the state by reducing its charge. In the United States, children adopted via the public system are already being cared for through foster care, and public agency adoptions are a key way that those children may exit the foster care system. In the U.S. ethnic minority children are overrepresented in the foster care system and the majority of those adopted are more than 5 years old at the time of their adoption (U.S. Department of Health and Human Services, 2009: 7). Overwhelmingly, children adopted from the foster care system are adopted by someone they know: 54% of those adopted in 2007 were adopted by a foster parent and 30% by a relative. By contrast, private adoptions in the United States are accomplished legally but without the same oversight established for public adoptions. They may occur either through the mediation of a private agency, or through a direct arrangement between birthmother and adoptive parent. International adoptions are also private from the perspective of the country the child is being moved to (the 'receiving country,' discussed below), since the children adopted do not move through the domestic foster care system prior to being placed.

Domestic/International

Thirdly, one can also distinguish between domestic and international (also called transnational or intercountry) adoptions. Domestic adoptions occur within the borders of a nation, while international adoptions involve a parent or parents from one country adopting a child from another country. As in migration scholarship, the country from which the underaged migrant comes is referred to as the 'sending country,' and the country to which he or she migrates is called the 'receiving country.' International adoptees are literally child migrants, and much of the paperwork required to formalize their presence in their new home is identical to that completed by migrants. Presently, international adoptions are expected to occur under the auspices of an international Hague Convention, formally entitled the "Convention of 29 May 1993 on Protection of

Children and Co-operation in Respect of Intercountry Adoption" (The Hague, 1993).

Domestic adoptions in the U.S. peaked in 1970, and more recently demand has moved overseas. International adoption formally began as a humanitarian project during midcentury in the context of wars in Europe and Asia (the Spanish Civil War, World Wars I and II, and the Korean War). But there was a veritable international adoption boom at the turn of the twenty-first century. Worldwide, the number of international adoptions increased by 42% between 1998 and 2004; some countries saw much sharper increases, and as one example, during that same period the number of international adoptions to Spain increased by 273% (Selman, 2009: 578).

Kin/Strangers

Three other important characteristics cross-cut these categorical distinctions. First, any of these adoptions may occur between relatives or between strangers. Stepparent or kin adoptions are included in national statistics as well and are difficult to separate out from 'stranger adoptions.' Kin adoptions, also called relative adoptions, may occur in any one of these adoption 'types' whether informal, formal, domestic, international, public, or private.

Race and Adoption

Second, any of them can be defined as transracial or racially 'matching.' Transracial adoptions are those in which a parent and a child physically differ in skin color, hair texture, and other features that are interpreted as racial identity. Most transracial adoptions involve white adoptive parents and minority adopted children, due both to racial hierarchies and ideologies and to the makeup of the foster care system. Since at least the 1950s, white parents have adopted children of color often from a stated position that race should not matter and the children need homes (Dubinsky, 2010).

Some minority communities have mobilized against those assumptions, including two strong statements in the U.S. in the 1970s. In 1972, the U.S. National Association of Black Social Workers issued a 'Position Statement on Trans-Racial Adoption' arguing that white parents are unable to teach African-American children the strategies that they would need to know in order to 'survive in a racist society.' In 1978, the Indian Child Welfare Act established that Native American tribes had specific collective rights and that Indian children's needs should ideally be understood as they relate to the community. (A 2013 Supreme Court ruling in the 'Baby Veronica' case appears to have weakened the ICWA.) Both communities were acting from a long history of having their children removed – African-American children into the foster care system and Native American children into boarding or residential schools.

International adoptions are frequently transracial, and this observation is reflected in current policy in many sending countries, in some cases directly derived from language used in Article 20 of the United Nations Convention on the Rights of the Child, which prioritizes "the desirability of continuity in a child's upbringing and … ethnic, religious, cultural and linguistic background."

Irregular Adoptions

Third, each kind of adoption may be evaluated as to whether it adheres to local norms or is 'irregular.' For example, some informal adoptions are traditional fostering arrangements, and others exploit children for labor. Perhaps more controversially, some international adoptions, while accomplished legally, may also be irregular and some legal scholars have criticized them as akin to traffic (Smolin, 2005) because of the lack of transparency with which poor people's children are deemed to be adoptable.

As is clear from this rapidly complicating picture, adoption is not simple, nor can it be well understood without considering several other related phenomena: informal fostering, public agency foster care, the orphaning or abandonment of children, the institutionalization of children, racial discrimination, the availability of reproductive technologies and their implications for adoption (such as embryo adoptions – when extra embryos, left over from the IVF cycle, are implanted into unrelated women's bodies – or the adoptions that may occur if a surrogate mother gives birth to the child of an intended mother, by contract), and other familiar demographic concerns such as ideal number of children, gender preference of children, and the like. The following section examines the data available for understanding adoption.

Demography of Adoption

Understanding adoption involves several related demographic analyses. Firstly, simply counting adoptions and determining how many occur can be challenging, given the regulatory patchwork and the differences between public and private adoption outlined above. We will also obtain a better understanding of adoption through considering related issues such as fertility rates and changes in rates of unmarried mothers placing their children for adoption.

Data and Collection Issues

Since the 1990s, there have been approximately 118 000 adoptions per year in the U.S., down from an all-time high in 1970 (Davis, 2011: 4). Data from 2000, 2007, and 2008 for the United States indicate that for each of those years, approximately 40% of the year's total adoptions (about 50 000) occur through public child welfare agencies, approximately 13% (about 18 000) were international, and almost half (47%, or just over 60 000) were from other sources: private agencies, stepparents, or tribes, for example (Child Welfare Information Gateway, 2011: 4). Contrast these figures with those from the 1980s and early 1990s when 16% of adoptions originated from public agencies (Flango and Flango, 1995, cited in Child Welfare Information Gateway, 2011: 14). In 2007, of the more than 50 000 children adopted from foster care, 23% were adopted by relatives and 69% were adopted by a foster parent (possibly including relatives) (Vandivere et al., 2009).)

But where does this data come from? The answer is surprisingly complicated. In the U.S., government data is available for public agency adoption. However, much of

private domestic and international adoption cannot be statistically tracked:

> There is no single source for the total number of children adopted in the United States, and there is currently no straightforward way of determining the total number of adoptions, even when multiple data sources are used. No single agency is charged with compiling this information, and agencies that do collect adoption-related data do so for their own purposes and therefore count adoptions differently (e.g., by court cases filed, birth certificates modified, adoptions completed by public agencies), which makes aggregation difficult.
> Child Welfare Information Gateway, 2011: 5

Similarly, several scholars have remarked upon the significant challenges in collecting accurate data on international adoptions (Kane, 1993; Selman, 2002; Weil, 1984). Records, particularly in sending countries, can be incomplete and obtaining data from receiving countries – such as immigration data for the 'orphan visa' in the U.S. – has proven more reliable.

Standardizing Measures

Whether one counts adoption applications, actual adoptions completed, or the population of children in foster care, or whether one measures changes in attitudes toward adoption, all of these methods could yield different figures and might not represent the current state of affairs. Thus, once adequate data has been collected, the problem of comparison also arises.

Peter Selman has proposed some different possibilities for standardizing measures of international adoption in particular. He suggests that international adoptions could be standardized either against the annual number of live births or per 1000 population (Selman, 2002: 207). Such a standardization would allow us to determine whether the countries with the largest overall numbers of international adoptions (the United States holds the top spot) also have the highest *ratios* of international adoptions to live births. In fact, Selman's results – using an 'adoption ratio' of the number of adoptions per 1000 live births – show that European countries had much higher ratios than the United States. In 1998, Norway's adoption ratio was 11.2 (p. 212) and the U.S.'s was 4.2, although the U.S. had 15 774 international adoptions and Norway had 643 that year (p. 213).

A similar measure can be developed to compare numbers of adoptions from specific sending countries. Again, Peter Selman offers two options: considering adoptions in relation to 100 000 population aged 0–4, or standardizing against births. His calculations show, for example, that although the large numbers of children from China are notorious, compared to the total number of under-5 children in China they are less significant than the figures from less populous countries like, in its day, Romania. He also found that standardizing against births allowed him to see that high birth rates do not explain adoption (the 'surplus story'). South Korea, China, and Eastern European nations, which have below-replacement birth rates, nonetheless continue to be significant sending countries (Selman, 2002: 216). Countries like Russia (peak year 2004), China (peak year 2005), Guatemala (peak year 2007), and Ethiopia (peak year 2010) have more recently been the most numerically significant sending countries (Selman, 2010: 7, 8; 2009: 578).

Causes of/Justifications for Adoption

The figures and calculations presented above complicate some of the commonly held assumptions about why children are adopted and lead to new and useful questions. The story about adoption today holds that in Western countries, fertility rates have declined and the population of adoptable infants domestically has decreased, leading to a rise in international adoption (Lovelock, 2000: 908; Selman, 2002: 206). Let us examine these statements more closely.

Infertility

Infertility is said to drive adults' desire to adopt. Certainly postponement of child bearing leads to an increased risk of infertility (*see* Infertility: Demographic Aspects). This story helps to explain the high incidence of international adoption; Selman and his colleagues report that "The proportion of international adopters who are primarily motivated by infertility is usually put at about 75 per cent" (Haworth et al., 2010: 136).

However, low fertility is not the only proximate determinant of a decision to adopt internationally. For example, single people or same-sex couples may not be biologically infertile but may choose to adopt rather than pursue alternative strategies. Evidence from U.S. adopters of Chinese children (Rojewski and Rojewski, 2001) and Catalonian adoption applicants (Font Lletjòs, 2008, cited in Marre, 2009: 231) suggest that infertility may motivate fewer than half of certain subsets of international adoptions. Instead, complex desires for a multicultural family or to help a needy child may be part of the picture (*see* Family Size Preferences).

This is also the case for adoptions that are other than international. The National Survey of Adoptive Parents (2007–08, United States) found that 52% of surveyed parents "noted they were unable to have a biological child, an issue for 18 percent of the intercountry adoptions, 14 percent of the foster adoptions and 20 percent of the private adoptions. Eighty-one percent wanted to give a child a permanent home" (Davis, 2011: 16).

Adoptions from foster care, stepparent, or kin adoptions may be motivated rather by an existing connection with a child. Informal adoptions, too, are not necessarily motivated by infertility. Anthropological research on informal adoptions has found many other possible and overlapping motivations: to strengthen relationships between the birth parent and foster parent, to have company for one's children or more hands to share the chores, or to demonstrate social prestige and generosity.

Thus, increasing rates of infertility are relevant, but not the whole explanation, for what motivates people to adopt. In other words, an infertile person who does not want to have a child will not be motivated to adopt by his or her infertility.

Changing Sources of Adoptable Children

It is also said that prospective adopters currently desire specific kinds of children: young, healthy, and possibly of a particular

race or gender. One reason that is sometimes offered for high rates of international adoption is that such children are no longer available domestically. What would explain a decrease in the available population of infants? The legalization of abortion (1973 in the U.S.) and increase in availability of birth control meant that fewer unwanted children were born. Perhaps more importantly however, changing social mores meant that through the 1970s and 1980s in the U.S. it became much more accepted for a woman to raise a child as a single mother. It was not that single women were no longer having children – it was that they were less likely to place those children for adoption. Prior to 1973, 9% of single mothers placed their children for adoption (19% white and 2% black); from 1973 to 1981 this figure dropped to 4% and from 1982 to 1988 to 3% (Briggs, 2012: 7).

Another complication is that there are actually children available in the public systems of the U.S. and other countries. But these children are not infants, and many of them are minorities. Scholars have identified significant racial disparities in foster care populations. Indigenous children are overrepresented in foster care in the U.S., Canada, and New Zealand, but the problem is particularly acute in Australia, where 24% of the children in foster care but only 5% of the child population overall are indigenous (Tilbury, 2009: 62). In the U.S., African-American children are less than 20% of the child population but almost 50% of the foster care population, and "Once removed from their homes, Black children remain in foster care longer, are moved more often, receive fewer services, and are less likely to be either returned home or adopted than other children" (Roberts, 2002: vi). Over the course of their childhoods, African-American children have an 11% risk of entering foster care, and Native children a 15% risk (Wildeman and Emanuel, 2013).

That is only a partial picture, however, because it is not only that there are fewer infants 'available' domestically but also that we perceive there to be a surplus of infants available overseas. On one hand there is a narrative about war, disaster, or HIV orphans needing homes (the unusual case of China is an outlier here, in which population policy has directly led to the abandonment of numerous female infants; *see* Family Planning Programs: Feminist Perspectives). However, the majority of children adopted from abroad are not orphans, and have living relatives (Graff, 2008). There is also a Malthusian tinge to this narrative: In many developing countries, fertility rates are higher than they are in the 'receiving countries' of international adoption, and in some cases poor parents cannot care for all their children – particularly when war, natural disasters, or HIV are also features of the landscape. As Selman concludes, "It is, however, evident that the major sources [of internationally adopted children] have not been the poorest or highest birth rate countries, that patterns persist long past the 'crisis' and that demand for children is also a key factor" (Selman, 2002: 218, 219).

Thus, changes in the 'supply' of adoptable children domestically may motivate some adults to look overseas for an available child. The demographic makeup of the 'adoptable' minor population is not an explanation for why adoption happens, however. It is rather an attempt to document differences in that population that might explain why people who have already decided to adopt choose to do so through the public system, privately, or internationally.

Since 2004, numbers of international adoptions have fallen substantially, although numbers of applications to adopt have continued to grow (Selman, 2010, 2009). Decreases since 2004 in numbers of adoptions around the world do not appear to reflect a decline in demand but rather a shrinking supply of available children (reductions in China and Russia and a moratorium on adoptions from Guatemala have all had significant impact) (Selman, 2009: 575, 581). One reason this supply is shrinking is because almost half of the 40 primary source countries for international adoptions over the past 15 years – "places such as Belarus, Brazil, Ethiopia, Honduras, Peru, and Romania – have at least temporarily halted adoptions or been prevented from sending children to the United States because of serious concerns about corruption and kidnapping" (Graff, 2008: 60). Additionally, in 2008 the Hague Convention finally entered into force in the United States, the country with the highest numbers of international adoptions worldwide. This voluntary regulation meant adoptions from Guatemala among other places would stop. That same year, the global economic crisis began, and those economic straits are affecting fertility rates in general as well as people's desire (or financial eligibility) to adopt. International adoptions to the United States have dropped substantially since these changes, from 17 000 in 2008 to 11 000 in 2010 (Child Welfare Information Gateway, 2011: 25).

Neither infertility nor changes in the supply of adoptable children explain why adoptions happen today. They would not happen where there is no desire or demand for them. Although the stated purpose of adoption is to provide a family for a child, many iterations of adoption today look more like a demand for children rather than efforts to protect them. One way of resolving this tension is to argue that parents who want a child are the best thing for a child, justifying the high demand for children as a measure of child protection (Leinaweaver, 2013). And indeed, the primary cause of adoption – the proximate determinant – is that an adult feels socially compelled to, or is driven to, submit to the often invasive and lengthy procedures required of prospective adopters. Desire for a child, and the feeling that an adopted child will satisfy that desire, is what motivates adoption (*see* Children, Value of) (Lozano and Kossoudji, 2009: 20).

Adoption and Cultural Transformation

What remains to be understood is the relationship between adoption and culture. This final section will focus on changes in how adoption itself is socially understood and on the social changes that affect how adoptees are perceived and understood.

Despite the dominant narrative that adoption is first and foremost a measure to protect a child, adoption is understood and conceived of as a family-making project by those adults who enter into it. They do so out of a desire to be a parent, and an adoptive parent in particular. To understand this desire, we need to examine cultural features of adopting societies (*see* Fertility and Culture: Anthropological Insights). For the early stages of adoption – the years preceding it and the first several years of a child's life – we must conceptualize adoption itself as a family-making project. What this means has shifted over time. The profile of a desirable adoptable

child has changed along with it. In the nineteenth century, older children were desirable adoptees because they could collaborate with a family work project, such as a farm. But by the 1930s children were valued for their sentimental qualities and thus ought not to be 'useful,' leading to a desire for helpless babies (Zelizer, 1985: 168). Furthermore, the rise of psychological and child development theories about bonding grounded adults' wishes for a younger child who was more impressionable and had had fewer effects of being institutionalized. Along with these changes have gone legal changes that determine the secrecy and openness in adoption. In the United States, adoption was in the nineteenth century an accepted practice, with records available to adult adoptees; but between 1930 and 1980 almost all states closed adoption records. Initially, this was said to protect adoptive families from birth parents who wanted to contact or claim their children. Later, as a greater pressure to openness prevailed in the 1960s and beyond, the justification shifted and sealed records were defended as a promise of secrecy that had been given to birth mothers upon surrender of their children (Samuels, 2001: 370, 371).

Other recent changes have to do with who is permitted to adopt a child. In many countries single persons or gay and lesbian couples are permitted to adopt openly. This, combined with blended families already familiar from divorce and remarriage or stepparent adoption, and interracial adoptions, has all led to a greater diversity in the makeup of families. In some quarters this is a development to be viewed with great enthusiasm: the normalization of family diversity might mean greater social support for families once viewed as unusual, such as those including single mothers or multiracial families. Yet there is also cause for caution. Simultaneously with the greater normalization of adoption and other kinds of nontraditional families, other social changes are occurring whose impacts on adoptive families are as yet unclear. For example, as internationally adopted, transracial adoptees grow up, and international migration has boomed, adoptees may be 'misidentified' as immigrants, something observed in Europe (Hübinette and Tigervall, 2009: 344; Leinaweaver, 2013) (*see* Migration: Cultural Aspects; Assimilation of Immigrants). In this sense, it is possible that a multicultural context is also a risk factor for transracially adopted youth as long as that multicultural context is characterized by discrimination against minorities.

A final, and critical, cultural transformation is to be found in scholarship and policymaking on adoption. Up till now, most research on adoption has been conducted by adoption professionals and in some cases, adoptive parents. The cohort of adopted adults is growing and research that originates from and takes seriously their standpoints and perspectives is likely to transform the way that we think about adoption. It is even rarer to consider the perspective of birth parents (but see Modell, 1986), but similarly essential to expand the kinds of questions that we ask about adoption, its causes, and its consequences.

In conclusion, the one constant in adoption appears to be its diversity over time. Adoption today looks very different than it did even two decades ago, to say nothing of the differences from its origins in nineteenth century civil code or Roman law. And those changes reflect broader transformations that are of great interest to demography. As Davis has observed, "Although adoptions represent a small portion of family growth, from a demographer's point of view it is significant" (Davis, 2011: 3). Demographers are well positioned to track the ways in which supply of children and demand for adoption have shifted over time. And doing so will continue to yield productive findings about changes in family structure, the value of children, and the consequences of poverty and discrimination.

Abstract

Adoption transcends all cultures and has existed over centuries. This article charts the evolution of adoption from Moses in the Bible to contemporary domestic and intercountry adoption practices. Internationally and globally it has evolved in response to changing political, economic, and social circumstances, acting as a solution to social problems of the time. An adoption order is the most radical order that can be made in the field of family law for it involves the permanent transfer of all legal rights and responsibilities from birth parents to a new family.

Introduction

Adoption is the process by which the legal relationship between a child and his or her birth parents is severed and a new relationship established with adoptive parents. An adoption order is the most radical order that can be made in the field of family law for it involves the permanent transfer of all legal rights and responsibilities from birth parents to a new family. Once an adoption order is made, parentage is completely and irrevocably transferred to the adoptive family. Adoption demonstrates a sense of optimism about society's ability to engineer happy outcomes for children while at the same time, it deprives birth parents of any legal parental status and historically, has rendered them strangers to their children. At best, adoption conjures up promises of family life for adults and children who otherwise would have been without it. At worst, it represents the most Draconian form of state intervention in family life (Smith and Logan, 2004). This article considers the evolution of adoption and makes some suggestions for practitioners working in this field. It also refers mainly to the specifics of Anglo-American societies. Adoption in other parts of the world raises different socioeconomic, political, and cultural issues that require separate consideration, e.g., Latin American and African societies. However, space prevents me from doing so here.

Because adoption involves the raising of children by parents and families other than those to whom they were born, it is a complex and emotional subject. It profoundly changes the course of everyone's life, for the rest of their life. For children, it changes their primary relationship with their birth parents and can raise concerns about why they were given up for adoption with profound curiosity about their origins. The impact on birth parents and adoptive parents can be equally profound as their lives are changed forever.

For this reason, adoption has attracted immense public and political interest. It is a controversial and sensitive subject, touching on issues of love and loss, nature and nurture, identity, ethics, and human rights. Transracial and intercountry adoptions (ICA) and adoptions without parental consent further magnify these issues.

Adoption raises important questions concerning the family and the relationship between biological and social parenting. Traditionally in Western society/culture, the blood bond has served as the basis for the creation and continuation of family kinship systems, and common sense notions of 'blood is thicker than water' and 'our own flesh and blood' prevail to this day. Adoption challenges these assumptions for it represents a remarkable relationship between the legal definition and effects of an adoption order and the way in which adopters and their children develop bonds of love and attachment through the everyday social construction of family life.

Modern adoption has adapted rapidly to social change and throughout history it has acted as a solution to social problems of the time. Adoption today is diverse and complex, and globally, the scope and meaning of adoption varies significantly.

In contemporary Western societies, there are two types of adoption; domestic and intercountry. In the UK, the majority of adoptions are domestic and ICA account for only 4% of the total number. In contrast, domestic adoptions in other European countries are rare and ICA more commonplace. In the US, both types of adoption feature with the US adopting more children both internationally and domestically than the rest of the world combined (Pertman, 2013). US domestic adoptions have much in common with the UK as in both countries the fate of children in the care of the state has become the major policy issue.

The Social Construction of Adoption – A 'Legal Fiction'

The meanings attached to adoption are considerably more complex than a straightforward legal mechanism would suggest. Adoption has to be understood as both a legal reality and a socially constructed phenomenon, which is influenced by the historical, political, cultural, and social context in which it is located. Adoption, like everything else, takes its meaning from the world around it and adoption means different things in different times. This is evident in cross-cultural studies of adoption (Silk, 1980; Terrell and Modell, 1994; Berebitsky, 2006) and examinations of how domestic adoptions in the US and UK have developed.

Since its legal origin in 1926 in the UK (1930 in Scotland), adoption has acted as a barometer for social change, reflecting, and responding to issues of public and political interest, representing something of a litmus test in respect of much larger issues such as: what 'the family' should look like, how should

 http://dx.doi.org/10.1016/B978-0-08-097086-8.28002-1

the state intervene when a parent is unable to look after their child, and when family life is fundamentally a private matter?

In order to understand parenthood that is a contractual arrangement based on law in a culture in which parenthood is created by birth, Judith Modell contends that the constructed relationship must be as much like the biological one as possible (Modell, 1994). Traditional adoption in Western societies was thus constructed to mirror biological kinship – a socially and legally endorsed form of kinship equivalent to blood ties with the particular practice of closed adoptions and secrecy acting to support this perspective. Adoption legislation in the UK and US continue to regulate the construction of adoptive families through 'legal fictions' – eradicating a child's ties to birth kin and incorporating him or her into the adoptive family 'as if' begotten, and the parent 'as if' genealogical (Smith and Logan, 2002, 2004). The Adoption Act, 1976 and the Adoption and Children Act, 2002 in the UK perpetuate the fiction that adopted children have no family other than their adoptive family (Ryburn, 1997; Smith and Logan, 2002). The Hague Convention similarly utilizes legal fictions with regards to ICA.

Critics have objected to the wording contained in these pieces of legislation, claiming they support a construction of adoption that denies the ongoing significance of birth family members in children's lives. In its review of adoption law, the Law Commission of New Zealand (2000: 43–44) recommended that the 'legal fiction' incorporated in their legislation is a 'repugnant and unnecessary distortion of reality' and should be removed from future legislation.

Sir Henry Maine, a British jurist in the nineteenth century, was the first to acknowledge the 'fictive' nature of adoption:

> We must try to regard the fiction of adoption as so closely simulating the reality of kinship that neither law nor opinion makes the slightest difference between a real and an adoptive connection.
> (Maine, 1861: 239, cited in Modell, 1994)

The law is a powerful force reflecting societal values and determining who can and cannot adopt. In an endeavor to reflect biological kinship alongside assumptions of what constitutes a 'normal' family, adoption had historically been the prerogative of heterosexual married couples and legislation had outlawed the adoption of children by unmarried, including gay and lesbian, couples (Logan and Sellick, 2007). Single people were, however, able to adopt. It is only since the introduction of the Adoption and Children Act, 2002 that lesbians and gay men have been allowed to adopt in the UK and it continues to be illegal in some States in the US. Nonetheless, adoption by same sex couples is growing in the US but an uneven legal landscape, due to laws prohibiting same sex marriage, means that adopted children are without the rights and protection extended to children adopted by heterosexual couples (Tavernise, 2011).

The Evolution of Adoption

Adoption transcends all cultures and has existed over centuries. The story of Moses in the Bible represents the first account of an adoption. Forms of adoption are also recorded in ancient Greece and Rome where its roots lie in legal mechanisms for the acquisition of heirs and transmission of property.

A historical examination of adoption practice in the Western tradition reveals a number of distinct periods, each one reflecting the preoccupations of the time, with adoption serving different functions at different times (Triseliotis et al., 1997).

In the nineteenth century period of industrialization, adoptions were concerned with providing security for children orphaned or born illegitimately. Disease, death, and destitution lead to increasing numbers of children placed in workhouses, the conditions of which were so poor there were serious concerns about infant mortality. Consequently, children were 'indentured' into families who would clothe, feed, and educate them in return for helping out the family with its work. These arrangements represented a protoform of adoption (Howe, 2009) and were evident in the UK and US. In some American states they became legalized through specific acts of legislature in the midnineteenth century, and the adoption statute passed in Massachusetts in 1851 became the model for subsequent adoption legislation in the US. In Britain, they remained *de facto* adoptions with no legal security. It was not until 1926 that the first adoption law was introduced in England (1930 in Scotland) – the impetus for which was the large numbers of orphaned or illegitimate children born during and after the First World War. During the period between the two world wars a number of societies were set up in both the UK and US to arrange such adoptions and by 1929 all states in the US had adoption legislation. In order to protect the privacy of the adoptive family and to protect the child from the stigma of illegitimacy these adoptions were 'closed' with no contact between the child's old and new families and the child was issued with a new birth certificate. The emphasis was on a fresh start and a clean break from their families of origin.

For much of its history, adoption has been seen primarily as a solution to the problem of illegitimacy, unwanted pregnancy, and the stigma and shame attached to these. After the Second World War, adoption was viewed as a solution to the problem of married couples' infertility, and the emphasis was on meeting the needs of infertile couples rather than those of the baby. Known as the era of 'the perfect baby for the perfect couple' great emphasis was put on matching the child to the adoptive parents in an attempt to ensure as much similarity as possible between the placed baby and the new family.

In both the US and UK, the 1960s and 1970s witnessed a shift from adult-centered practice to one that focused on the child. A number of factors were influential in this move toward a more child-centered approach: the legalization of abortion, the availability of contraception, the increasing acceptance of single parenthood, and availability of state welfare benefits led to a huge drop in the number of young White children available for adoption. At the same time, the number of couples wanting to adopt was on the increase. It was also becoming increasingly apparent that children who were not able to be looked after by their birth families, were drifting in the public care system, with no long-term plans for their future. The 1980s saw the emergence of the 'permanency movement' in the US and UK, in which adoption became seen as a positive placement of choice for these children, many of whom had

suffered early adversity. As a consequence, older children, children with disabilities, non-White children and sibling groups were increasingly considered for adoption, with an emerging mantra that 'no child is unadoptable'.

Domestic Adoption Today

In the US and UK adoption has now evolved into a means of providing a solution to the needs of children in public care. These children are unable to return to their birth family due to the risk of maltreatment or neglect, resulting from serious parental problems such as drug and alcohol misuse or mental health problems. It has become identified as child centered, long lasting and potentially advantageous over other placement options such as long-term foster care and residential care. Research has demonstrated that it has positive outcomes, particularly for infants and very young children (a discussion of adoption outcomes is complex and outside the scope of this article; see Rushton and Dance, 2003, Selwyn et al., 2006; Steele et al., 2008).

In the UK, the age and profile of children being adopted has changed considerably. In 1971 there were 21 495 adoptions, most of which were baby adoptions. However, domestic adoptions of infants are now rare and the last 40 years has witnessed the growth of adoption as a placement option for older children. Many of these have special needs and histories of abuse and neglect and the adoption of 'looked after' children is now a central feature of the child care system in the UK.

In 2013, the number of children adopted from care in England was 3980 of which only 2% (90) were under 1-year-old. The majority (74% or 2960) were between 1 and 4 with the average age being 3 years 8 months. These adoptions account for only 5% of the total number of looked after children, most of whom are placed in foster care. The majority of adopters are still heterosexual couples; 90% compared to 10% single adopters and 6% same-sex couples (www.baaf.org.uk/res/statengland).

Adoption in the UK is highly regulated with every local authority serving as an adoption agency. The voluntary sector also has an important role, both in facilitating adoptions and in the provision of postadoption support. The adoption process has become an active legal contest between the state and birth parents centering on the culpability of the parents in respect of abuse and neglect and whether they can or cannot change to adequately care for their child. While adoptions with parental consent are legally possible, rarely do parents agree with the local authority that they have abused or neglected their child and in these cases consent is dispensed with by the court as the best interests of the child require it (Simmonds, 2012).

From an ethical and human rights perspective adoption continues to be a controversial subject (Harris-Short, 2008). Dispensing with parental consent and severing the legal tie of children to their birth family through adoption is seen as an infringement of human rights in many European countries and therefore not an option available. In these countries long-term fostering and/or residential care are favored over domestic adoption as placements of choice.

From Secrecy to Openness in Adoption

The most significant change in the nature of adoption concerns the move away from confidential, closed adoptions to a more open approach. More than anything else, the issue of adoptee–birth family contact has had a far-reaching impact on the changing face of adoption today and has dominated adoption policy and practice since the mid-1980s.

For many years the 'secrecy is best' philosophy dominated practice in domestic adoptions in the UK and US. However, it is now acknowledged that this fresh start and clean break approach to adoption naively ignored the complexities that adoption would create for birth families and adoptive families with research and personal testimonies emerging to challenge the simplicity of this approach (Triseliotis, 1973; Winkler and Van Keppel, 1984). Origins, identity, and heredity continue to be important (Howe and Feast, 2000) and it is now acknowledged that many of the psychological problems that may affect adopted people, adoptive parents, and birth parents are directly related to the secrecy or anonymity of the closed traditional form of adoption.

The move toward a more open approach to adoption was also fueled by the 'search movement', initially led by Florence Ladden Fisher in 1971 in the US and rapidly spreading to Canada and the UK. 'Identity politics' and the rise of new social movements at the time informed her ideology of searching based on adoptee rights. However, their inability to gain access to adoption records by claiming constitutional rights led to a second generation of search leaders with an ideology based on psychological need (Carp, 2002). Led by three adoption researchers in the US (Baran et al., 1974) their work emphasized that searching stemmed from "an innate curiosity about their genealogical past" (Baran et al., 1974: 532) and the need to establish a clearer sense of identity. A third generation of the movement emerged in 1996, exemplified in the activism of 'Bastard Nation'. This group challenged mainstream adoption activist organizations with their emphasis on 'psychological need' and the facilitation of unions between adoptees and their birth relatives, and instead, once again, focused on adoptee rights.

In non-Western cultures, open adoption is not a new phenomenon. Adoption arrangements are publicly acknowledged and both sets of parents are well known to each other. This notion of a dual connection is an important aspect of adoption in the Pacific Islands of Oceania (Silk, 1980) and similarly, in the Maori system of New Zealand, adoptions are public knowledge and children's relationships with their birth parents well known and understood (Rockel and Ryburn, 1988). Generally, Black and Asian, Hispanic and Native American families are far more familiar than White communities with the idea of contact and in fact, expect it, whether in short- or long-term child care arrangements.

Postadoption contact arrangements between adopted children and their birth family members are a central feature of most contemporary domestic adoptions in the UK and US and may involve face-to-face meetings with birth relatives (direct) or contact by phone, letters, e-mail (indirect) (Parker, 1999, Neil and Howe, 2004, Grotevant and McRoy, 1998).

However, contact is a complex area of work and practice in openness has evolved to include a number of key dimensions

indicating that 'indirect' and 'direct' contact oversimplify the complexity of openness as it has developed over the last decade or more. Focusing on what form the contact should take (e.g., letters or meetings) neglects the nuances and complexities inherent in both forms of practice. For example, both forms of contact may or may not involve some form of mediation (by the adoptive parents or the placing agency), may vary according to the level of identifying information the parties may hold about each other, and, crucially, may vary in the extent to which the children are involved. New forms of contact emerging through the use of social networking sites such as Facebook, further adds to the complexity (Smith and Logan, 2004). Within the research community 'communicative openness' (Brodzinsky, 2006) – the openness of adoptive parents in thinking and talking about adoption has been identified as equally, if not more important than what kind of contact takes place. Whatever its form, the debate about openness has led to a polarization of views within the adoption community and an adversarial relationship between advocates for, and critics of, openness. While few would challenge the need for openness about children's preadoption history, there is much less certainty about the circumstances in which adoption with some form of continuing contact should be planned. Nonetheless, in the UK there is now a clear expectation that children will have *some form* of contact with their birth relatives (Lowe et al., 1999, Parker, 1999) and the Adoption and Children Act, 2002 specifies that contact issues have to be thoroughly explored prior to the making of an adoption order. Similar issues apply to US domestic adoptions and there is emerging evidence that postadoption contact is becoming a feature of ICA.

Intercountry Adoption – The Globalization of Adoption

ICA feature mainly in the US, the Nordic countries, Spain, and other parts of western Europe. Originally it emerged as a global legal phenomenon involving formal agreements between sending and receiving countries as a response to the needs of orphaned children as a consequence of war. After the Second World War, international adoption was largely about the movement of children from countries in Europe and Japan to the US. These altruistic motives for ICA continued from the mid-1950s with large number of children from the Korean and Vietnamese wars being adopted overseas (Selman, 2009). By the 1970s ICA were well established in the US, mainland Europe, and Australia, and was seen primarily a service for childless couples in the West and the children were victims of poverty rather than war. This period witnessed a drastic decline in the availability of babies for domestic adoptions in Western countries due to increasing access to contraception and abortion and a growing acceptance of single parenthood.

It is estimated that since Second World War, ICA have been a solution for approximately one million children rendered parentless due to political, economic, and social circumstances in less developed countries. The opening of China and Russia in the 1990s saw an 'explosion' of ICA with 410 000 children adopted by citizens of 27 countries between 2000 and 2004. In Russia the break up of the Soviet Union was a significant factor and in China it was the discovery of the impact of the one-child policy, which lead to the abandonment and subsequent institutionalization of mainly female children. Under the Ceausescu regime in Romania, women had to have a minimum of four children, which led to many children entering institutions because their parents could not support them. ICA were seen as a preferable option to the negative consequences of institutional care (for detailed analyses of ICA, see Selman, 2009, 2012a,b).

After decades of steady growth, ICA are now on the decline and the number of ICA dropped by nearly 50% between 2004 and 2010 (Selman, 2012a). Paradoxically, however, the numbers of children sent abroad for adoption from the US is on the increase! These are mainly Black American babies whose birth mothers are choosing to have them adopted – mainly in Canada and Holland, in the belief that they will escape the evils of racism. In 2009, 315 American children were adopted internationally. While considerably fewer than overseas orphans joining US families, this nonetheless represents a threefold increase of American children being adopted overseas since 2004!

The global decline of ICA is not due to fewer orphans worldwide nor less demand from prospective parents but increasing regulation and a growing concern about irregularities in practice. Initially viewed as a humanitarian exercise in rescuing children from countries ravaged by war or natural disaster (e.g., after the earthquake in Haiti in 2010), more recently, ICA have generated concern as a form of Western imperialism, with commercial interests taking priority over the rights and welfare of children or birth parents. Children in ICA are frequently seen as objects of commodification, available for a price that only wealthy parents can afford. The extreme case of commodification is the rumor that children are being stolen from poor countries and sold for their organs in rich ones (Khabibullina, 2009).

The 1993 Hague Convention for the Protection of Children was introduced in an attempt to regulate adoption arrangements in both sending and receiving countries to ensure that policies and practices became child centered. Yet, there have been continuing reports of irregularities in adoption and of adoption as a cover for child trafficking. In the past decade a number of adoptive parents in the US have been found guilty of killing their adopted child, and in 2009, Russia suspended the adoption of Russian children by American families after Artyom Savelyev, a 7-year-old adopted Russian boy was rejected by his American mother and sent back alone to Russia. David Smolin, who discovered that his two adopted daughters from India had been stolen, has written extensively on the topic of irregularities in ICA (Smolin, 2006, 2011). He argues for much stronger regulation of practice, without which, ICA should be abolished. In contrast, advocates of ICA argue that, if reformed, ICA could increase once more and form a key component of globalized child welfare in the same way that adoption has been seen as the placement of choice for abused children in the US and UK (Bartholet, 2011).

Nonetheless, research outcomes demonstrate that ICA can offer new hope to children who might otherwise spend their childhood in institutions (Juffer and van Ijzendoorn, 2009). The challenge is to continue this support for individual children while encouraging the development of adoption and foster care in the child's country of origin.

Race, Ethnicity, Identity, and Belonging: Contemporary Issues in Adoption

Race and ethnicity in adoption bring to the foreground political, social, psychological, and legal issues calling into question our ideas of racial and ethnic boundaries, identity, and belonging (Barn and Kirton, 2012; Lind, 2012; Hubinette and Andersson, 2012). According to the UN Convention on the Rights of the Child (UNCRC, 1989), a child's ethnic, religious, cultural, and linguistic background should be paid due regard in adoption, as should the desirability of continuity in a child's upbringing (Article 20). Article 16b of the Hague Convention on the Protection of Children and Co-operation in Respect of Intercountry Adoption (HCCH, 1993) contains similar wording. Both conventions also stipulate that ICA should only take place after possibilities for placing the child within the country of origin have been explored (UNCRC, 1989, Article 21b; HCCH, 1993, Article 4b).

However, adoption has been associated with violations of the rights of ethnic minority groups. In both the US and the UK, the practices of transracial placement and racial matching within domestic adoptions have a history of fierce debate with proponents for and opponents against transracial adoption. Dating back to the 1960s, several factors form the backdrop of this debate: the disproportionate representation of minority ethnic children in the public care system, the 'unavailability' of suitable minority ethnic adopters, concerns about adoptees' racial/cultural identity and the 'suitability' of White parents to raise racially competent children (Barn and Kirton, 2012).

Research in the 1980s in the UK, established that while children placed transracially successfully met developmental milestones, questions remained about the long-term impact on the child being dislocated from their ethnic and cultural heritage (Gill and Jackson, 1983). The adoption of Black children by White parents was seen as evidence of the colonization of the Black community by removing its children and 'making them White'. As a consequence, a commitment to same race placements became dominant in policy and practice. Only relatively recently has this policy been challenged on a number of grounds: the acknowledgment that society is now a complex mix of ethnic groups, identity is not fixed and singular but changes over time and in different contexts and, particularly significant in the UK, the serious delays experienced by many minority ethnic children in care, which can result in them not being placed for adoption at all (Simmonds, 2009).

In the UK, the legal requirement (under the 1989 Children Act and 2002 Adoption and Children Act) is to give due consideration to the child's religious persuasion, racial origin and cultural and linguistic background with strongly worded guidance that this should not prohibit transracial placements nor lead to delay while an ethnic match is sought. However media headlines suggest that White parents are being denied the opportunity to offer suitable adoptive homes to minority ethnic children in need (for a comprehensive discussion of the UK context, see Barn and Kirton, 2012) and currently the English Government is seeking to establish a policy that will minimize the consideration of a child's ethnicity and, in consequence, promote transracial adoption of minority ethnic children in the UK.

Similar debates prevailed in the US until the Multi-Ethnic Placement Act 1994 and the Inter-Ethnic Adoption Provisions 1996 were passed to introduce legally enforced color blindness. The aim was to remove the barriers to transracial placements though this has not had the desired effect (for a comprehensive discussion of the US context, see McRoy and Griffin, 2012).

When adoption takes place between different countries, questions of identity, belonging, ethnicity, and culture become even more prominent. Despite this, for many years ICA were not considered transracial placements in some countries. Unlike the UK and US, for example, there has been no debate about whether White people should adopt people of color in Sweden. The societal and cultural norm has been one of official antiracism and color blindness and only in the last decade have ICA been identified as transracial adoption, a view resisted by many adoptive parents and agency officials (for a comprehensive discussion of the Swedish experience, see Lind, 2012; Hubinette and Andersson, 2012).

A number of studies have addressed identity in ICA, for example, Volkman in Sweden (2005), Dorow in the US (2006), Howell in Norway (2009), Gray in Australia (2009), and Richards in the UK (2012). All support the argument that ethnicity and culture are fluid and flexible concepts, meaning different things to different people within specific communities and change across space and time. With support, adoptees are able to create their own narratives of belonging and construct their own sense of identity. Nonetheless, this is a complex process and narratives of transnational adoptees highlight the "contingent struggles and ambiguities of intercountry adoption" (Richards, 2012: 110).

Conclusion

This article has outlined the changing nature of adoption. Internationally and globally, it has evolved in response to changing political, economic, and social circumstances. In some form or other, controversy and conflict have featured throughout its evolution and will no doubt continue to mark the development of adoption policy and practice for years to come (Simmonds, 2012).

Abstract

The world is poised for a major educational revolution centered on adult education and lifelong learning. By 2050, the number of persons with 65 years of age and older will be greater than children five and under. 'Nontraditional' students nearly equal the number of traditional students enrolled in higher education and adults are seeking educational and learning opportunities for a multiplicity of reasons. The growing and diverse group of adult students and learners presents opportunities and challenges to educators across settings.

Emergent Population of Adult Learners

A steady increase in average life expectancy in recent years, coupled with the aging of the baby boomer generation, has given rise to a growing number of adults with 60 years of age and older in the United States. In the US, the average life expectancy is 75.7 and 80.8 years for men and women, respectively (U.S. Census Bureau, 2012). This changing demographic is not unique to the United States. According to the Organisation for Economic Co-operation and Development (OECD, 2011), which represents a consortium of over 30 countries across North and South America, Europe, and the Asian-Pacific region, a newborn girl in 2008 is expected to live up to 82.0 years, which is 11 years more than a baby girl born in 1960. A baby boy is also expected to live up to 76.5 years, which is 11 years more than the one born in 1960 (OECD). As a result, the proportion of older adults in many societies is growing. In 1960, only 8.5% of the global population was 65 years of age and older, whereas this percentage rose to13.8% in 2005 (OECD, 2007). "Very low birth rates in developed countries, coupled with birth rate declines in most developing countries, are projected to increase the population ages 65 and over to the point in 2050 when it will be 2.5 times that of the population ages 0–4" (Haub, 2011).

The increase in life expectancy over the last century was concomitant with an increase in education attainment. In 1910, 13.5% of adults of 25 years of age and older in the United States attained a high school diploma as compared to 84% in 2000 and during that same time period the percentage of persons achieving four or more years of college rose from 2.7 to 25.6% (National Center for Education Statistics, 2001). This trend is indicative of attainment rates throughout the world which evidence improvement across both advanced and developing countries and are reflected in indicators such as a decrease in a worldwide 'nonschooling' rate of 47.1% in 1950 to 14.9% in 2010 and increase in secondary schooling for children of 15 years of age and older from 5.2 to 25.9% over the same years (Barro and Lee, 2012). The 'educational revolution' of the nineteenth and twentieth centuries centered on formal, consistent schooling of children and is credited with substantial public benefits such as modernization and economic growth (Baker et al., 2011). Currently, we are poised on the brink of a subsequent educational revolution centering on adult education that may also spur economic growth and lead to healthy, active aging throughout adulthood thereby producing positive public health benefits. The demand for adult educators has risen (Wyatt and Hecker, 2006) as the current educational revolution is spurred on by the increasing number of adults and their continued desire to remain engaged in formal and informal educational and learning experiences for a variety of reasons.

Adults' participation in educational opportunities may be the result of professional requirements (e.g., need to master new content or technology, occupational change). Many middle-aged and older adults are working longer and in 'encore careers' (Metlife, 2008). Within the context of an expanded life span, it is estimated that adults will spend an average of 41 years working in a professional capacity and 12 years in 'retirement' assuming an initial starting work age of 25 years (Gallup, 2012). However, it is anticipated that by 2020 the number of workers of 55 years of age and older will increase by 38% (Bureau of Labor Statistics (2013)) and 75% of workers of 50 years of age and older expect to have a retirement job in the future (Brown et al., 2010). With prolonged employment in adulthood comes a need for continuing education due to shrinking opportunities for high school graduates and increasing educational requirements (e.g., degrees, certifications) set forth by employers across occupational settings (Society of Human Resource Management, 2012).

In addition to motivations centered on work, 'nontraditional' adults pursue formal and informal education for diverse personal circumstances including pursuit of personal and leisure interests as well as a desire to learn and connect with others (Lakin et al., 2008). This emerging audience is creating new opportunities as well as challenges for educators and organizations to meet diverse for adult educational content and learning needs. The first steps already underway have been recognition of lifelong educational opportunities and expanding our understanding of how adults learn.

Lifelong Learning and Andragogy: Recognizing the Context of Adult Learners

Operating at a broad conceptual level, 'lifelong learning' refers to active learning throughout the life course and places

emphasis on the learner (Hager, 2011). The conceptual basis of lifelong learning has been and continues to be heavily influenced by 'three progressive sentiments: the individual, the democratic, and the adaptive' (Bagnall, 2001). As a result, individual development and growth throughout the life span, social justice, and cultural change are at the forefront of lifelong learning theory, practice, and advocacy in order to achieve individual- and societal-level benefits of education (Bagnall).

In contrast to lifelong learning, 'adult' or 'lifelong' education is more narrowly focused on specific elements of education, bringing to mind 'curriculum, teachers, teaching modes, and types of educational providers' (Hager, 2011). For almost a century, adult learners have been recognized as qualitatively different from younger learners. Early work on the science of adult learning focused on 'whether or not adults *could* learn' (Merriam, 2001), however, the field expanded to address how adults learn best and ways to support adults' lifelong learning. Knowles bid 'farewell to pedagogy' in 1970 promoting a distinct field of inquiry into adult learning and education called 'andragogy.' Andragogy reflects the science of adult education that aims to distinguish the needs and best practices related to adult education. The field of andragogy continues to advance today and as described by Merriam (2001) is based on several key premises centered on (1) adults' need for self-directed learning that reflects internal motivations, (2) focused learning linked to an applied need that supports the learner's life context and social roles, and (3) accumulated experiences that serve as a resource for the adult learner.

Although andragogy-related research has progressed, practice advances in the field have not been as rapid. As noted by Imel (2001), "Statistically, in the past 2 decades, adult students have changed the face of postsecondary education. What is not clear is the extent to which their presence has changed instructional practices. As a group, adult students have special concerns that should be addressed in the postsecondary classroom. However, these concerns must be addressed in light of the individual needs of each student." At times, 'nontraditional' and 'adult' students have been described separately in the literature; however, there are overlapping characteristics and motivations of these students. Nontraditional students are often identified by the presence of at least one of the following demographic characteristics: full-time employee, part-time student status, 1 year or greater post high school graduation, lacking high school diploma, financial independence from parents, and being parents themselves (Compton et al., 2006). Adult students tend to have select, work-related goals and view their primary identity as an employee rather than a student and as a result adult students have a greater likelihood of participating in a distance education program and programs that have specific vocational outcomes (Compton et al.). Whatever the label, these learners represent a diverse group with varied needs. Adult learners tend to seek formal education following life transitions and are often prompted by workplace and career pressures (Compton et al.). All adult students are faced with multiple roles as a result of seeking adult education (Kasworm, 2008), however, men and women are likely to have differing reasons for postsecondary education (Deutsch and Schmertz, 2011). Women in particular are likely to face greater external factors and multiple life roles that create added hardships (e.g., financial strain, continued child care and household responsibilities; Deutsch).

Lifelong Educational and Learning Benefits and Opportunities

Educational experiences throughout the life span support whole-person health and well-being. Early formal education in particular seems to set the course of key later life outcomes. These outcomes include indicators of health, functional ability, and survival and are hypothesized to reflect several potential mechanisms of influence such as increased cognitive functioning and human capital and ultimately access to resources and improved health decisions throughout the life course (Baker et al., 2011; Latham, 2012).

Educational benefits continue throughout adulthood and recognition of the benefits and need for continuous education throughout the life span have resulted in the emergence of concepts including lifelong education and lifelong learning. It is increasingly acknowledged that adult educational experiences can be of a formal or less formal nature. Lifelong education and learning may occur in a traditional institution of higher education, within distance or online environments, in the workplace, and via informal classes and experiences (e.g., travel). Although sometimes used synonymously, the terms 'lifelong education' and 'lifelong learning' do not necessarily represent conceptual similarity. 'Lifelong education' typically denotes more formal, structured educational experiences, which rise to some criteria, whereas 'lifelong learning' tends to refer to more broad-based learning that occurs across a variety of contexts (Hager, 2011). "Over the last half-century, lifelong learning has transformed from an avocation to an imperative. Lifelong learning has become intertwined with the labor market, making it difficult to find a better job or keep up with technology-driven industry standards without returning to school, potentially several times over the course of a lifetime" (p. 1; Council for Adult and Experiential Learning, 2012).

Once classified as 'nontraditional,' adult learners of 25 years of age and older "have comprised close to 40 percent of the college-going population [for the last two decades], spanning a range of backgrounds and experiences, from Iraq and Afghanistan war veterans and GED credential holders to 55-year-old professionals and skilled workers in career transition" (American Council on Education, 2013). This depiction highlights the diversity of 'adults' seeking educational opportunities. Within formal institutions of higher education, there is a growing recognition of adult students and examples exist of longstanding programs. For instance, begun in 1971, the University Without Walls at the University of Massachusetts Amherst supports 'nontraditional' undergraduate students by providing extensive advising and support services, assessment of prior experiences for credit, as well as enhanced program options and flexibility (University of Massachusetts Amherst (2013)). In a similar fashion, the Resumed Education for Adult Learners (REAL) program offered by Tufts University was originally created in 1970 to support young mothers returning to or beginning college by providing academic and financial resources (Tufts University, 2013). Rather than segregate adult learners, the REAL program purposefully integrates adult students in mainstream undergraduate programs and the program was opened to include men in 1976 (Tufts University).

Less formal options available for older adult learners are noncredit courses offered by programs such as 'Colleges for Seniors' and Osher Lifelong Learning Institutes (OLLI; The Bernard Osher Foundation, 2005). In the case of OLLI there are 116 programs across the United States offering noncredit courses encompassing academic- and leisure-related topics of interest to 'seasoned adults' of 50 years of age and older (The Bernard Osher Foundation). "Emphasis is placed on learning for the joy of learning and on keeping in touch with a larger world" (The Bernard Osher Foundation).

Benefits and opportunities related to lifelong learning and education are not limited to formal classroom settings, and many adult educational experiences are available outside of a traditional classroom. One classic example is the Road Scholar program, also known as 'Elderhostel' (Road Scholar, 2013). Beginning in 1975 and catering to older adults, this program offers 5500 educational and cultural tours across the United States and 150 countries that support whole-person wellness (e.g., cognitive, social, physical). Many educational opportunities for older adults also incorporate volunteerism and mentoring that benefit both the adult participant and members of his/her community. In the US, the Retired Senior Volunteer Program (Corporation for National and Community Service, 2013) and AARP Experience Corps (affiliate of the national AmeriCorps program; AARP, 2013) provide informal opportunities for older adults to engage in educational and enriching projects in their communities often within intergenerational settings. Interestingly, the European Commission recently combined separate age-specific learning programs, including an adult education-focused program, to create one overarching and integrated lifelong program focused on 'UK education, training, youth, and sport opportunities across Europe' (i.e., Erasmus + program; Ecorys and the British Council, 2013) with the intention of strengthening learner 'mobility,' establishing best practices, and securing policy change.

It is increasingly recognized that lifelong cognitive activity and engagement may help curb normative (typical) cognitive changes as well as the growing number of individuals experiencing nonnormative cognitive impairment and dementia that is fast becoming a public epidemic/concern. Brain 'exercise' can help maintain cognitive vitality and health, and formal and informal opportunities are increasing. Formal interventions typically target one type of cognitive skill (e.g., memory), imparting strategies for improvement (e.g., chunking of information) and occur in settings outside the home with other adults. Informal interventions are often technology-based and involve more individual work framed as 'games.' Scientific query into the efficacy of both types of training mechanisms and their impact on everyday functioning is still nascent.

Future Directions

Together, the increasing number of older adults, decreasing population of potential high school graduates to satisfy the job market, and the changing nature of work are contributing to a second educational revolution. Students who are 'nontraditional' in some aspect are now the majority rather than the exception within institutions of higher education (National Center for Education Statistics, 2002). Lifelong learning is becoming a cultural norm (Council for Adult and Experiential Learning, 2012). These realities create both opportunities and challenges for the field of adult education.

Early educational experiences as well as lifelong learning possess the potential to positively impact adult development and aging at the individual level, thereby promoting active aging in later life. These individual-level benefits also translate to group and societal levels as education can contribute to decreased health disparities. To reap these benefits, however, institutions and educators must recognize the potential of adult learners as well as identify methods to break down barriers to adults' educational and learning experiences. Three areas are particularly key: (1) understanding and embracing the diversity within the group of adult learners, (2) promoting whole-person wellness that is embedded in the ideal of continuous life span learning and within communities of learners, and (3) the thoughtful use of technology.

First, adult educators must recognize the diversity within the group of individuals representing adult learners. In general, adults (and particularly older adults) are a heterogeneous group who arrived at their stage in life after a multitude of experiences and environmental influences. Adult learners seek educational opportunities with varying motivations, expectations, skills and backgrounds, content needs, and contexts outside of the learning environment. "Because adults have competing lives, hopes, and realities, each semester of college involvement represents either a renegotiation or adaptation of themselves and their lives" (p. 29; Kasworm, 2008). As outlined by Fairchild (2003), adult learners balance an assortment of roles and associated responsibilities (e.g., family and caregiving responsibilities, career) in addition to being a student or learner. This reality can cause conflict and overload and in addition, adult students may receive less support from significant others in their educational pursuits compared to traditional students. At the most basic level, educational institutions and policy makers must address financial barriers (e.g., tuition, activity fees applied to all students, government aid policies) that constrain adult education; this may be particularly true for women (Deutsch and Schmertz, 2011) and older adults (Council for Adult and Experiential Learning, 2012). One example of a pilot initiative to combat the latter problem is the 'Lifelong Learning Accounts' that represent 'portable, employee-owned, and employer-matched accounts used to finance education and training' (Council for Adult and Experiential Learning). To address other practical barriers, enhanced and flexible student services should be implemented (e.g., web-based services, opportune office hours) and roles should be acknowledged as strengths and incorporated into the student experience to the student's advantage (e.g., draw upon relevant experiences and knowledge within courses; identify adult students for leadership roles; Compton et al.; Fairchild). Special programs can target psychosocial barriers frequently experienced by adult and 'mature' learners (e.g., 'anxieties about starting over,' worries about working with new technology, or 'competing with younger jobseekers'; Council for Adult and Experiential Learning). In general, we need new strength-based (Compton et al.) models acknowledging the contribution of adult learners (Kasworm, 2008), which create a 'sustaining academic community' (Deutsch and Schmertz, 2011) that

actively engages adult learners both inside and outside the classroom.

Second, enhanced integration and empowerment is needed in several respects. Paramount is the concept of lifelong learning throughout the life span rather than segmented learning within discrete age periods thereby leading to greater continuity of educational experiences. Additionally, moving from a single learner approach is valuable and collaboration among learners and the support of a broader supportive learning community can lead to enhanced outcomes not achievable by individuals. Furthermore, integration of formal and informal learning opportunities can expand the nature and method of educational and lifelong learning opportunities. The final aspect of integration is adoption of a whole-person approach that can assist adult educators in understanding the needs of adult learners and developing individualized plans to achieve goals across domains (e.g., social, intellectual; Compton et al.) and across educational and learning environments. For instance, 'prior learning assessments' can pinpoint already mastered material (for credit in formal educational settings; Council for Adult and Experiential Learning, 2012) and individual learning plans can target areas of development, both of which save time, frustration, and money. Together the philosophies underlying lifelong learning (i.e., individual, democratic, adaptive; Bagnall, 2001) can foster innovative and progressive opportunities and programs for lifelong learning and engagement throughout adulthood. An excellent example of this out-of-the box thinking is the 'Intergenerational School' for elementary-aged children, which incorporates learning opportunities for adults, including persons with dementia, with plans to integrate these educational experiences with the 'InterWell' health promotion program (Whitehouse, 2013).

Third, thoughtful use of technology to enhance and deliver adult education is critical. Currently technology may be a dual-edged sword when it comes to adults and use in an educational setting. Adult learners may be more likely to participate in distance education programs, however, these experiences can be isolating and distance programs can exhibit greater dropout rates (Bolliger and Halupa, 2012; Kruger-Ross and Waters, 2013). In addition, a 'digital divide' may be evident on individual and community/societal levels. On a personal level, new technologies can be intimidating for some adult learners (particularly older adults) because of a variety of factors including lack of exposure and familiarity, but perhaps more importantly due to psychological factors including computer-related and aging anxiety and self-efficacy (Jung et al., 2010). On a broader level, groups of individuals may be excluded as a result of resource (e.g., lack of computer access, low income) and practical constraints (e.g., availability of broadband in rural areas, functional disability) thereby imposing limitations on educational technology use (e.g., Choi and DiNitto, 2013). On the positive side, web-based support services (Compton et al., 2006) and instructional technologies (e.g., synchronous and asynchronous print, video, and audio tools; social media) can facilitate diverse adult learning styles, schedules, (Finch, 2011) and functional (e.g., mobility impairment) and sensory needs (e.g., vision or hearing challenges). In addition, unique experiences supporting adults' education and whole-person wellness may be possible through the use of technology such as 'virtual senior centers' (Selfhelp Community Services, Inc., 2013). These types of programs serve to greatly enhance access, as individuals do not need leave their homes. 'Gerontechnology' (technological applications geared toward aging audiences) is a growing field and technology is anticipated to play a larger role in not only adult education and lifelong learning, but also personal health and wellness promotion and intervention, as successive cohorts of adults become more familiar and facile with a range of technological tools.

As outlined in this section, capitalizing on adult learners' expertise and motivation to continue their learning across a variety of contexts will require an interdisciplinary and systemic approach to reduce barriers and increase access to lifelong educational opportunities. Professionals from fields such as education, psychology, gerontology, and computer/technology science are needed to understand and facilitate adult learners' needs. A systems approach is needed to help move theory and research to the realm of best practices and supporting policy. This approach requires input and collaboration from adult learners (e.g., openness to experience, advocacy, persistence), family and support systems (e.g., encouragement, role negotiation), employers (e.g., flexibility, purposeful professional development opportunities), institutions and organizations offering educational opportunities (e.g., enhanced support services, needed content offerings), as well as state and federal governments (e.g., policies, financial assistance) in order to support and promote continued learning throughout adulthood.

Adult Mortality in Developing Countries

Katherine T Lofgren and Haidong Wang, Institute for Health Metrics, Seattle, WA, USA

Abstract

Adult mortality measurement is becoming increasingly important as populations globally age and health-policy targets premature deaths in adult ages. Adult deaths are relatively rare events and can present a difficult challenge to estimate. This challenge is especially true in the developing world where vital registration systems to capture deaths in a country are often not well established or well functioning. This article aims to capture the available data sources for adult mortality and the methods to analyze those data sources as well as discussing the current levels and trends around the world.

Introduction

Developing countries around the globe have experienced fast demographic transition in the past six decades. We have witnessed decline in fertility and improvements in mortality. As a result of this impressive change, life expectancy at birth for both sexes combined in the developing world has increased from 42.28 years in 1950–55 to about 65.95 years in 2005–10 ("World Population Prospects: The, 2010 Revision," 2011). Much of this improvement is attributed to the fast decline in child mortality, which is defined as the probability of death from birth to 5 years of age. Billions of dollars have been invested in reducing child mortality among developing countries and great strides have been made since the United Nations Millennium Declaration was made by 189 nations in 2000. Millennium Development Goal 4 is set to reduce child mortality by two-thirds by 2015 from its level in 1990. Although it is true that the majority of the nations would not be able to achieve this goal by 2015 (Lozano et al., 2011; UN Inter-agency Group for Child Mortality Estimation, 2012), child mortality has declined significantly in the past two decades among developing countries thanks to the paramount efforts made by the governments, international organizations, and private donors. Unfortunately, less attention has been paid to monitoring and reducing preventable premature mortality in adult age groups.

In measuring adult mortality, two metrics are widely used to date: probability of death from age 15 to 50 and probability of death from age 15 to 60. The latter has gained more popularity since the publication of Global Burden of Diseases (GBD) Study by the World Health Organization, and later in the organization's annual World Health Report series. This measure succinctly conveys the risk of premature death in adult populations. An alternative is calculating the age-specific and sex-specific mortality rates. Stratifying mortality indictors by age and sex can help highlight inequalities and specific populations where the mortality burden is the highest. In this article, we employ probability of death from age 15 to 60 to measure the adult mortality rate.

Data Sources and Estimates

Three major sources provide estimates of adult mortality for all major populations in the world: United Nations Population Division through its biannual World Population Prospects report, World Health Organization through its World Health Report series, and more recently the Institute for Health Metrics, and Evaluation at University of Washington through its GBD, Injuries and Risk Factors Study.

To estimate adult mortality rate, ideally, raw data would come from civil registration systems that enumerate deaths in a country and record cause of death and other important epidemiologic information. Unfortunately, civil registration systems are expensive and require a large amount of infrastructure to be effective at capturing deaths in a population. Although some of these systems are established in developing countries, for a large portion of the developing world we have to rely on surveys and censuses to approximate mortality levels. Large survey series such as the Demographic and Health Surveys (*Macro International, Inc.*) often include questions aimed at approximating adult mortality in place of civil registration systems. This section aims to give detailed information about what data sources are available for developing countries and some of the considerations that should be taken with each as a source of mortality information.

Vital Registration Systems

Vital registration (VR) systems are a fundamental source of information regarding adult mortality in a population. Mortality rates can be calculated directly from the deaths and population information captured in the civil registration system. Although VR systems have the potential to provide the most reliable and continuous sources of adult mortality data, they often fall short of capturing all the deaths in a population. This undercounting of deaths is especially true of VR systems in the developing world where infrastructure and maintenance of the reporting systems is particularly difficult. VR-derived data are a critical source of reliable information. It is imperative that resources be channeled to better information systems in developing countries to create the most accurate estimates of mortality. Through better evidence and understanding regarding the age/sex patterns and causes of death, better health-policy decisions can be made.

Table 1 shows the developing countries with VR systems (as defined by active reporting within a 10-year window) and the estimated completeness of that system in 2010 as determined by data available in the GBD 2010 Study.

Table 1 Vital registration completeness for developing countries, 2010

GBD 2010 Region	Country	Completeness (%)	
Asia, Central	Armenia	92.8	(77.9–100.0)
	Azerbaijan	87.4	(72.8–100.0)
	Georgia	93.0	(78.4–100.0)
	Kazakhstan	93.1	(78.6–100.0)
	Kyrgyzstan	95.4	(81.4–100.0)
	Mongolia	84.4	(70.1–100.0)
	Tajikistan	79.6	(66.0–94.7)
	Turkmenistan	91.0	(76.1–100.0)
	Uzbekistan	84.2	(69.8–100.0)
Asia, East	Taiwan	95.8	(76.7–100.0)
Asia, Southeast	Malaysia	98.1	(87.9–100.0)
	Maldives	97.5	(86.6–100.0)
	Mauritius	97.4	(86.5–100.0)
	Myanmar	91.4	(78.4–100.0)
	Philippines	97.1	(85.9–100.0)
	Seychelles	99.1	(91.5–100.0)
	Sri Lanka	98.5	(89.2–100.0)
	Thailand	87.9	(75.0–100.0)
Caribbean	Antigua and Barbuda	93.9	(79.5–100.0)
	Bahamas	97.8	(86.6–100.0)
	Barbados	99.4	(92.6–100.0)
	Belize	98.0	(86.9–100.0)
	Cuba	97.6	(85.9–100.0)
	Dominica	98.3	(87.3–100.0)
	Dominican Republic	76.2	(63.8–90.4)
	Grenada	100.0	(100.0–100.0)
	Guyana	91.5	(77.1–100.0)
	Jamaica	98.1	(87.0–100.0)
	Saint Lucia	100.0	(100.0–100.0)
	Saint Vincent and the Grenadines	99.8	(97.6–100.0)
	Suriname	95.5	(82.1–100.0)
	Trinidad and Tobago	99.6	(94.9–100.0)
Latin America, Andean	Ecudar	93.2	(77.8-100.0)
	Peru	75.9	(62.0-91.8)
Latin America, Central	Colombia	92.3	(78.1–100.0)
	Costa Rica	99.3	(92.1–100.0)
	El Salvador	96.8	(84.1–100.0)
	Guatemala	99.2	(91.5–100.0)
	Mexico	98.8	(89.4–100.0)
	Nicaragua	94.2	(80.1–100.0)
	Panama	94.7	(81.1–100.0)
	Venezuela	98.9	(90.0–100.0)
Latin America, Southern	Argentina	98.7	(92.9–100.0)
	Chile	99.6	(95.4–100.0)
	Uruguay	99.4	(94.9–100.0)
Latin America, Tropical	Brazil	99.6	(95.3–100.0)
	Paraguay	81.6	(73.4–90.6)
North Africa/ Middle East	Algeria	94.7	(72.9–100.0)
	Bahrain	78.7	(55.7–100.0)
	Egypt	97.8	(80.5–100.0)
	Iran, Islamic Republic of	81.8	(58.4–100.0)
	Iraq	97.5	(78.9–100.0)
	Jordan	97.9	(81.0–100.0)
	Kuwait	99.9	(100.0–100.0)
	Libyan Arab Jamahiriya	80.6	(57.5–100.0)
	Morocco	46.7	(32.8–64.4)
	Occupied Palestinian Territory	61.3	(42.8–85.2)
	Oman	93.8	(71.3–100.0)
	Qatar	82.3	(58.4–100.0)
	Saudi Arabia	65.7	(46.2–91.0)
	Syrian Arab Republic	99.8	(100.0–100.0)
	Turkey	74.7	(52.8–100.0)
Oceania	Fiji	99.4	(90.5–100.0)
	Marshall Islands	80.1	(53.7–100.0)
Sub-Saharan Africa, Southern	South Africa	99.6	(93.5–100.0)

Completeness is defined as the percent of the deaths in a nation covered in the VR system.

Within the countries that are listed in **Table 1**, there are 35 countries with VR completeness above 95%, meaning that the registration system is estimated to capture 95% of the deaths of people aged 15 and above in the country. For systems that fail to capture all of the deaths in a system, the data must be adjusted to account for the bias using demographic methods. In 15 of the countries in **Table 1**, there is an estimated coverage of adult deaths below 85%. The method used to assess completeness of VR systems in adult populations is referred to as the death distribution method (DDM). Detailed information regarding the application of several specific types of DDMs can be found in Manual X which was published by the United Nations Population Division (United Nations. Department of International Economic and Social Affairs. Population Division and National Research Council (U.S.). Committee on Population and Demography, 1983). Three variants that are often used include the generalized growth balance method (GGB), the synthetic extinct generation method (SEG), and a combined method that employs both GGB and SEG. GGB and SEG were developed in the 1980s by Hill and Bennett & Horiuchi, respectively (Bennett and Horiuchi, 1981; Hill K, 1987). Hill and Choi build upon these methods to propose the combined variant in the mid-2000s (Hill K et al., 2009). Other efforts have been to identify the optimal age trims that should be used in estimating the completeness of a VR system (Murray C.J.L. et al., 2010). **Figure 1** below shows the distribution of VR systems in developing countries, delineated by whether the system captures at least 95% of the deaths in the country.

Of note in the figure is the clear lack of VR systems in the majority of Africa and much of Asia. Although both complete and incomplete VR data can be a useful source of information,

Figure 1 Vital registration systems in developing countries.

it is not available in much of the developing world. Only 65 of the 137 developing countries have operating VR systems in 2010, or 47% of the countries. Further, there has not been progress in establishing new systems; in 1980 there were 67 out of 137 developing countries reporting deaths through VR systems, 2 more reporting countries than we observe in 2010. Lack of functioning VR systems among developing countries presents a problem for researchers worldwide who are interested in the true level of mortality in these countries. Without information from VR systems, supplemental information from censuses and surveys that provide information on health and mortality has been utilized.

Censuses

Censuses are also an important source of mortality information, especially when small area mortality estimates are desired. Censuses are unique in their comprehensive nature and large sample size. Although censuses may include (theoretically) the entire population, they also are not targeted to estimate adult mortality as their primary purpose. Often the only question included for the estimation of adult mortality is the number of deaths in the household over a specific recall period (typically 12–18 months). With data on the entire population captured in the census and the number of deaths in a household, adult mortality can be estimated. It is important to note that asking respondents questions about the deceased age at death often includes recall error and age heaping. Some of the recall error and age heaping can be avoided by survey design, often event calendars, and culturally appropriate survey questionnaires can reduce both of these biases (Aday, 1989; Belli et al., 2001; Mukherjee and Mukhopadhyay, 1988).

Interestingly, census household deaths recall data can be corrected for underreporting in the same manner the VR data can be assessed and adjusted, using DDMs. A full compilation of completeness estimates and adult mortality estimates for census-derived death information is available online for the GBD Study at http://vizhub.healthdata.org/mortality/. Although censuses have large sample sizes, they often occur infrequently – especially in resource-poor settings. In addition to censuses, national and subnational surveys provide critical information on the most current trends in adult mortality.

Surveys and Survey Series

Surveys and survey series are the backbone of adult mortality estimation in developing countries. Surveys offer an opportunity to create targeted survey modules specifically designed to gain accurate information about mortality trends and levels in a community. Although they can provide an economic means to gain information compared to a VR system, they are often flawed. Sampling schemes must be designed correctly to capture a representative sample and often missingness and recall bias make the data unusable. Luckily, there are many well-conducted surveys to pull from and in some cases, a series of surveys conducted with similar modules and sampling frames. Survey series like the Demographic and Health Surveys conducted by Measure DHS (ICF International) and the Reproductive and Health Surveys conducted by the Center for Disease Control and Preventions often provide a consistent data source across countries and over time.

Survey data are typically released first as a report, which may include a few summary estimates of adult mortality. Ultimately, access to the microdata will provide the most information about mortality trends in the sampled population. Surveys can ask about adult mortality through several strategies. Similar to censuses, survey can also ask about deaths in the household in the last 12–18 months. Unlike most full censuses, surveys can also include more specific modules aimed specifically at mortality estimation.

Specific modules aimed at capturing adult mortality include sibling and parental survival histories. In a sibling survival history, a respondent is asked about the survivorship status of his/her siblings. Similarly, in a parental history a respondent is asked about the survivorship status of his/her parents. This information, in addition to the respondent's age, can be used to estimate mortality risks.

Sibling histories build off the well-established survey methods to estimate under 5 years' mortality by asking mothers about the total number of children they have given birth to and the number of children currently surviving (Feeney G, 1991; Myburgh, 1956; Rajaratnam JK et al., 2010; Sullivan, 1972). This mortality estimation technique relies on a mother reporting the mortality experiences of her offspring and was first developed by Brass and has gone through refinement over the subsequent years (Brass and Coale, n.d.; Rajaratnam J.K. et al., 2010). In contrast, sibling history modules in surveys require the respondent to answer mortality questions regarding his/her siblings. This is a useful extension of the summary birth history technique to estimate adult mortality when more reliable data sources are lacking. The respondent's age is used as an approximation of the exposure risk experienced by all of the respondent's siblings, with respondent's answering questions about how many siblings they have and the number of those siblings that are currently alive (Hill and Trussell, 1977). The exact methods to estimate adult mortality using these survey modules can be found in demography reference books including 'Manual X' and 'Demography: Measuring and Modeling Population Processes' (Preston et al., 2001; United Nations. Department of International Economic and Social Affairs. Population Division and National Research Council (U.S.). Committee on Population and Demography, 1983).

Sibling histories although useful can prove to be biased. Often respondents are unable to accurately recall the mortality status of all of their siblings, particularly in high-fertility populations. Further, respondents may legitimately not know the survival status of siblings, especially siblings that are much older and may be out of contact with the respondent. Beyond the obvious issues with recall bias, there is also the potential for high-risk mortality families where all siblings have died to be missed, referred to as zero-survivorship bias. Further, the survey sampling scheme may bias the results as large families with many siblings are more likely to be sampled (and sampled multiple times) compared to smaller families. To account for this sampling issue, weights can be applied to the responses based on the respondent's total number of siblings (Gakidou and King, 2006; Masquelier, 2013). Further refinements and applications of these methods have been made over the years,

making sibling histories a data source that can prove meaningful and enlightening when VR and censuses are lacking (Obermeyer et al., 2010).

Parental histories offer an analogous option to sibling histories described above except that the survivorship status is asked from the survey respondent's mother (or father) rather than their siblings. This can be especially challenging as survey respondents may not recall the survivorship of their parents, introducing recall bias. Further, young respondents cannot reliably identify if their caregivers are their biological parents, limiting the age group that can report on their parent's survivorship to those typically above age 15. One of the central underlying assumptions is that a parent's mortality risk is unassociated with their child's risk. The use of parental survival information to estimate adult mortality was first proposed in 1960 by Louis Henry (Henry, 1960). The methods were formally developed by William Brass and Kenneth Hill in 1973 (Brass and Hill, 1973). Through the following decades there was significant improvements and expansion of the methods, including the addition of time references for mortality estimates developed by Brass and Bamgboye (Brass and Bamgboye, 1981). There have been several applications of the method and attempts to improve survey-instrument methodology (Blacker, 1977; Luy et al., 2011; Timaeus and Chackiel, 1996; Timaeus, 1991). There are also further extensions of this method that require two surveys 5–10 years apart; in this case the mortality estimates specifically reference the intersurvey period.

Parental and sibling histories present similar strategies to estimate adult mortality. Both warrant consideration in data-sparse settings and should be used in combination and comparison when both are available. Although the aforementioned survey-based adult mortality estimation methods can provide estimates of mortality, many researchers have avoided using such methods because of the concerns about different biases inherent in these methods. In countries where only child mortality estimates are available, it is common to estimate adult mortality using a model life table system where both age pattern and level of adult mortality are dictated by the entry parameter, normally probability of death from birth to 5 years of age, and the selected standard life table (*MODMATCH*, n.d.; United Nations. Department of International Economic and Social Affairs. Population Division and National Research Council (U.S.). Committee on Population and Demography, 1983). The INDEPTH Network, a global network of health and demographic surveillance systems, has made significant efforts in collecting population health data in 49 surveillance sites throughout Africa, Asia, and Oceania. Although faced with small numbers (both vital events and exposures), data from these sites provide unique insights into levels, trends and age patterns of mortality for many low- and middle-income countries. Efforts are being made in generating model life table system based on data from the INDEPTH network and especially for populations affected with HIV/AIDS.

Levels and Trends of Adult Mortality in the Developing World, 1950–2010

There are various sources of information on country-level adult mortality risk, the probability of death from 15 to 60 years of age. In this section, the numbers cited are from the GBD Study 2010. More information on the collaborators, the structure, and the aims of the GBD Study is available online (http://www.healthdata.org/gbd). The information here is derived from the all-cause mortality GBD 2010 research of Wang et al. published in *the Lancet* (Wang et al., 2012). Continuous efforts are being made to generate regularly updated versions of the GBD Study, beginning with an update through 2013. For the most up-to-date estimates of adult mortality risk, child mortality risk, and other relevant demographic metrics consult the databases and visualizations available here (http://www.healthdata.org/gbd/data-visualizations).

Other sources of information on adult mortality include the estimates generated by the United Nations Population Division. Estimates from the World Population Prospects 2012 Revision can be found online at (http://esa.un.org/wpp/unpp/panel_population.htm) or through the World Bank at http://data.worldbank.org/indicator/SP.DYN.AMRT.MA.

Heterogeneity in Adult Mortality among Developing Countries

Globally, adult mortality in the developing world has been improving at a fast pace since 1950. The GBD 2010 Study found that female adult mortality, the probability between ages 15 and 60, decreased from around 314 per 1000 in 1950 among all developing countries to about 140 per 1000 in 2010. Similarly, male adult mortality decreased from around 357 per 1000 to 214. In other words, adult mortality rates in the developing world have been declining at about 1.3% and 0.9% annually in women and men, respectively. Such summary measurements mask the great heterogeneity among countries in the developing world. In 1950, the highest estimated female adult mortality in the developing world can be found in Burundi, at 478 per 1000. This means nearly 50% of the 15-year-old adults would not live to their 60th birthday assuming they will experience the same set of age-specific mortality rates observed in 1950. At the same time, the lowest female mortality was observed in Qatar at 131 per 1000, an incredible 265% difference. For males, the highest adult mortality rate can be found in Equatorial Guinea, where it was 565 per 1000. In the same year, Qatar has the lowest male adult mortality rate at 184 per 1000. Over the past six decades, both absolute and the relative differences in adult mortality rate between countries with the highest and lowest values have increased, indicating increasing health disparities among these populations. In 2010, the highest adult female mortality rate is estimated to be in Haiti where an earthquake that claimed over 222 000 lives has driven the mortality rate up tremendously. The second highest female adult mortality was from Swaziland, where it was about 526 per 1000. In the same year, the lowest female adult mortality rate among developing countries was from Cyprus at about 42 per 1000. The relative difference between the highest and lowest female adult mortality rates has increased from about 265% in 1950 between Burundi and Qatar to about 1152%. Similar difference can be found for male adult mortality rate. In 2010, the relative difference between the highest adult mortality from Lesotho and the lowest adult mortality from Qatar was 751%, a much higher value compared to the relative difference of 207% between the aforementioned Equatorial Guinea and Qatar.

Figure 2 Annualized Rate of Decline in Male Adult mortality, 1970–2010.

There is even greater heterogeneity in the country-level changes in adult mortality over the past six decades based on the GBD 2010 Study. Among men in the developing world, Peru experienced the fastest rate of decline in adult mortality from 1970 to 2010 at an annualized rate of 3.37%. This impressive rate of change helped lower the male adult mortality rate in Peru from 436 per 1000 in 1970 to about 113 per 1000 in 2010. Similar stories of success can be found in South Korea, Singapore, Jordan, Macau, and Maldives where annualized rate of decline in male adult mortality rate exceeded 2.5% for the last four decades. During the same period, 33 developing countries have seen increase in male adult mortality rate, many of which are from the Sub-Saharan African regions. Swaziland, Mozambique, and Lesotho experienced increase in male adult mortality rate at 1–2% annually since 1970. Yet, when we look at periods of 1970–90 and 1990–2010, a different story appears. For all three countries, the increase of adult mortality has been concentrated in years between 1990 and 2010. For Mozambique and Lesotho, adult mortality has been improving from 1970 to 1990. The trend reverted in the late 1980s and mortality started to increase sharply until the early 2000s. This is largely due to the HIV/AIDS epidemic in the region. Take Mozambique as an example; the crude death rate due to HIV/AIDS for men raised sharply from about 1.6 per 100,000 in the late 1980s to about 516 per 100 000 around its peak in 2006. Figure 2 shows the annualized rate of decline in male adult mortality rate for the two periods: 1970–90 and 1990–2010. Based on Figure 3, it is clear that majority of the developing countries have experienced slowdown in improving adult mortality rate during the two periods. Only 57 countries have improved the annualized rate of decline in male adult mortality rate in the period of 1990–2010 comparing to what they have experienced in the period of 1970–90.

On the other hand, the distribution of annualized rate of decline in adult mortality has changed considerably in the past six decades. Figure 3 shows the annualized rate of decline for women in adult mortality rate for the periods of 1950–70, 1970–90, and 1990–2010. It is clear that the heterogeneity in change of adult mortality has increased over the past 60 years. In the period of 1950–70, only five developing countries had deteriorating female mortality rate. The mean annualized rate of decline in adult mortality is well over 1.2% for this period, with a range of −1.17 to 3.96%. Fast forward to the last 20 years; the spread of the distribution is much wider. Annualized rate of decline in female adult mortality rate ranged from −4.62 to 6.1%. Bahrain, China, Maldives, South Korea, Qatar, and Rwanda have made significant strides in reducing female adult mortality rate in this period, all of which have a 3+ percent annualized rate of decline.

At the same time, many countries have suffered increase in adult mortality. Most significant increase in female adult mortality was observed in Haiti, Lesotho, Mozambique, Swaziland, South Africa, and Zimbabwe from 1990 to 2010. All except Haiti (earthquake in 2010) have been affected by the HIV/AIDS epidemic as discussed earlier.

Heterogeneity in Change by Sex

Another phenomenon we have observed is the changing sex mortality differentials among countries. In most country-years, adult mortality rates among men are higher than those among women. There are exceptions though. For example, male adult mortality rates were about 15% lower than female adult mortality rate from 1950 to the mid-1970s. When only focusing on 1970 and 2010, we can find that sex mortality differentials have increased in 111 out of 144 developing countries included in the GBD, Injuries and Risk Factor Study. Sri Lanka, Venezuela, Dominica, and El Salvador have experienced the most significant increase in sex mortality differentials. In Venezuela, male adult mortality rate was about 39% higher than female adult mortality rate in 1970. This relative difference has increased to 153% in 2010. Similarly in El Salvador, the relative difference between male and female adult mortality rates was about 36% in 1970, and this differential increased to about 140% in 2010. It is

Figure 3 Distribution of annualized rate of decline in adult female mortality.

important to note that for most countries that experienced an increased sex mortality differential, both male and female adult mortality have improved during the same time, with female adult mortality improving at a much faster rate than male adult mortality. In El Salvador, for example, the female adult mortality rate decreased from 192 per 1000 in 1970 to about 104 per 1000 in 2010. At the same time, the male adult mortality rate only managed to improve from 261 per 1000 to 252 per 1000. A full list of the adult mortality results related to the GBD Study is available online with associated visualizations (GBD, 2010: http://vizhub.healthdata.org/mortality/).

Challenges Ahead

It has been shown that adult mortality has made significant progress among developing countries in the past six decades. Yet significant heterogeneity between sexes and among countries still exists. At the same time, long-term improvement masks the heterogeneity in change of mortality by a shorter time period. The rise of the HIV/AIDS epidemic not only threatens the long-term improvement in human mortality but also presents challenges in accurately capturing the true level of adult mortality as the traditional indirect estimate on methods are not well tuned to deal with such situations.

Adult Mortality in Eastern Europe and the Former Soviet Republics

France Meslé, INED, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

From 1965, a strong divergence in life expectancy appeared between Eastern and Western European countries. While life expectancy continued to progress in the West, it stagnated or even reduced in the East. The crisis was especially strong for males at working ages, due to the increase in mortality from circulatory diseases and external causes, with a major role of alcohol. Moreover from the mid-1980s to the late 1990s, countries of the former USSR experienced very large fluctuations of adult mortality, successively due to Gorbachev's antialcohol campaign and its rebound, followed by the deep economic crisis after the transition to market economy. Rapidly after the fall of Berlin Wall, progress resumed in Central European countries, followed by Baltic countries and more recently by Russia and Ukraine. This new progress was mainly due to a decrease in circulatory mortality at all ages. Despite these more favorable trends, the gap in mortality at adult ages between East and West remains important and affects older and older ages.

After World War II, health improved dramatically across Europe with the spread of antibiotics and the large-scale use of immunization. Progress was greatest where life expectancy was lowest. Southern European countries, like Italy and Greece, as well as Central and Eastern European countries, like Russia and Romania, which had lagged far behind in the 1940s almost caught up the most advanced Northern or Western countries (Vallin and Meslé, 2001). In the mid-1960s, all European countries had completed the second stage of the epidemiologic transition as defined by Omran (1971) and had eradicated infectious mortality, especially among young children. They were entering the third stage of man-made and degenerative diseases. In point of fact, mortality from circulatory diseases, traffic accidents, and alcohol abuse was stagnating or increasing almost everywhere at that time. In the West, however, the relative slackening of progress did not last, and by no later than the early 1970s, life expectancy was again on the rise, due both to a reversal of trends in man-made diseases and an accelerated decrease in circulatory diseases. The gains achieved in the West did not spread to Central and Eastern Europe. To the contrary, life expectancy in all Eastern European countries began to plateau or even decrease, especially for males. This huge gap between two parts of Europe continued to widen for three decades, resulting in a yawning divide by the mid-1990s. The evolution of mortality at adult ages, especially working ages, was the main driver of the divergence. During the 1990s, however, unfavorable trends reversed in all Central European countries and in the 2000s progress also started in European republics of the former USSR, thanks to an important decrease of mortality at all ages. Despite this recent progress, mortality at working ages remains very high in most Central and Eastern European countries in comparison with the Western ones.

Health Crisis in Central and Eastern Europe: The Major Role of Adult Mortality

Prior to the mid-1980s, general life expectancy trends were highly comparable in all Eastern and Central European countries (**Figure 1**). Nowhere were they good, but the acuity of the situation differed by country and sex. The worst case was that of males in the republics of the former USSR, where in the five republics represented here (Estonia, Latvia, Lithuania, Russia, and Ukraine), a fall from 1.5 to 3 years occurred in male life expectancy between 1965 and 1984. For females, the decrease was less pronounced but nevertheless there for Russia, Ukraine, and Latvia, while life expectancy was stagnating in Estonia and increasing but slowly in Lithuania. In the Central European countries, Hungarian and Bulgarian males registered the worse results with a decrease of 1.6 and 0.8 years, respectively, while life expectancy was stagnating for males in the other four countries (Czech Republic, Poland, Romania, and Slovakia) and only slowly increasing for females, region-wide.

From the mid-1980s, a sharp distinction appeared between the republics of the former USSR on one side and Central European countries on the other. In the former, trends in life expectancy became very chaotic while remaining very similar. After a period of improvement in the wake of the antialcoholism campaign launched by Gorbachev in 1985 just after coming to power, life expectancy slowly declined as the campaign effects faded. The deterioration accelerated sharply in 1993–94 (or 1995 for Ukraine) as all countries entered the severe economic crisis following the sudden change to a market economy. After the initial shock, life expectancy began rising again, but for Russia and Ukraine, at least, the upturn was short-lived and life expectancy sank again, whereas in the Baltic countries, a continuing rise suggests that they were entering a new stage of progress. Finally in the late 2000s, new progress appeared in Russia and Ukraine.

In Central Europe, the situation appears more favorable as one country after another has resumed its health progress. As early as 1988, trends in the Czech Republic reversed and life expectancy increased very rapidly. Likewise Poland and Slovakia in 1991, Hungary in 1993, Bulgaria and Romania in 1997. As the long-term trends were everywhere more unfavorable to men than to women, the upturn was more spectacular for male than female life expectancy. But females made also substantial gains, with a clear acceleration of the rate of increase in life expectancy in the late 1990s.

The unfavorable long-term trends in Eastern and Central Europe have already been extensively studied (Bourgeois-Pichat, 1985; Meslé, 1991; Okolski, 1993; Meslé and Hertrich, 1997). All these changes in life expectancy were mainly driven by changes in mortality at working ages.

Figure 1 Sex-specific trends in life expectancy in Central European countries and republics of the former USSR since 1965.

Figure 2 displays changes in age-specific male mortality in three countries, Poland, Estonia, and Russia, before and after the upturn. Consequently, the reference year varies from one to another country: 1991 for Poland, 1998 for Estonia, and 2005 for Russia.

In the three countries, the period of decline is characterized by a sharp distortion of the mortality age structure with a significant increase at adult ages, between 25 and 65 (Figure 2). Below age 15, there was a significant reduction of mortality risks while above age 70, death rates stagnated. Whatever the country, the major role played by adult ages in the unfavorable trends appears here clearly. The worsening is especially impressive in Russia where male mortality at age 50 was multiplied by 2.3 in 40 years, but the deterioration was also very important in Poland (a multiplication of 1.7 at age 45 but in 26 years only), or in Estonia (1.9 at age 45 in 33 years).

The changes in death rates, which occurred since the upturn in the three countries, are more equally distributed among all ages. Except old ages, death rates were considerably reduced. Once again the progress could seem less important in Russia, but considering that the reversal occurred in 2005 only, the reduction observed in 5 years is notable. The new stage that these different countries are entering one after the other appears to be one of a general improvement in health at all ages, and is no longer concentrated in a period of life as was the case for the worsening at specifically adult ages.

All these changes in mortality age structure depend on trends in causes of death. To study cause of death trends, we

Figure 2 Changes in male mortality age structure during a period of deterioration and a period of improvement in Poland, Estonia, and Russia.

use reconstructed series of deaths by cause that allow to get rid of the ruptures caused by the changes in classification of causes of death (Meslé et al., 1996; Fihel et al., 2010; Meslé et al., 2012). Deaths were gathered in seven large groups of causes.

As for changes in mortality age patterns, the period 1965–2010 is divided into two subperiods that are different for each country and correspond to the decrease and increase of life expectancy at birth, respectively. For each subperiod, we calculated the contributions by age groups of seven groups of causes to changes in life expectancy (Andreev, 1982). **Figure 3** gives the contribution for each age group and each group of causes.

As expected from age pattern changes, the decrease in life expectancy was closely correlated to the rise in mortality at working ages while, everywhere, progress in infant mortality checked the decline (upper panel of graphs in **Figure 3**). In Poland, mortality from circulatory diseases was the main cause of health decline at adult ages. In Estonia and Russia, in addition to the important role played by these diseases, external causes contributed to the life expectancy decrease significantly.

Looking at the period of improvement (lower panel of graphs in **Figure 3**), it comes as no surprise to see that mortality from circulatory diseases was the main determinant of the upturn in life expectancy in Poland, where gains in mortality from this cause account for 54% of the total. In this period, gains are rather equally distributed between adult age groups whereas in the previous period, losses were more concentrated on relatively young age groups. The phenomenon is quite different in Estonia and Russia: in these two countries external causes are mainly responsible for the progress that has been recently observed. This group of causes explains 40% of the gains in Estonia and 43% in Russia versus 36 and 35%, respectively, for circulatory diseases. Furthermore the decrease in mortality from external causes is especially important at young adult age groups. Finally in the two countries of the former USSR, the gains observed in this last period of improvement almost mirrored the losses registered in the previous decades, even if in Estonia, gains due to the decrease in mortality from circulatory diseases are expanding to older ages.

Looking at male trends in Poland, it is clear that this country has now entered a new step of health transition and was successful in the reduction of circulatory diseases, the so-called cardiovascular revolution (Meslé and Vallin, 2006). These results were already clearly shown for all the Central European countries (Meslé, 2004). In Estonia and Russia, however, male trends remain uncertain. Considering the importance of gains at rather young ages for external causes, it could be feared that these countries are just dealing with a new phase of fluctuations, comparable to what was observed from the mid-1980s to the mid-1990s (see Section Fluctuations and Mortality at Working Ages in the Former USSR) and that this recent health improvement will not be sustainable. Indeed the recent favorable trends could be related to new antialcoholic measures, which were taken in the recent years and could be very short lasting (Shkolnikov et al., 2013).

Fortunately, female mortality trends allow to be a little more optimistic for the future (**Figure 4**). Age and cause components of the life expectancy changes in the period of improvement appear completely different of those that prevailed during the period of deterioration. As for males, unfavorable trends were mainly due to a stagnation or even an increase of mortality rates between ages 25 and 60. On the contrary, not only in Poland but also in Estonia, recent progress is much more related to a decrease of mortality at older ages (over age 60), almost totally due to gains against circulatory diseases. Even if this is still less clear for Russia, the process could seem comparable (Grigoriev et al., 2014). In all these countries, the future challenges are now shifting to older ages (see Section An excess mortality shifting to older ages).

Fluctuations and Mortality at Working Ages in the Former USSR

The wide fluctuations in life expectancy that have occurred in the republics of the former USSR since 1985 have also been widely discussed in the literature (Shkolnikov and Nemtsov, 1997; Leon et al., 1997; Shkolnikov et al., 1998; Gavrilova et al., 2001, 2002). Changes in adult mortality were the main determinants of these fluctuations again. The Russian case, taken here as an example is the most emblematic.

In order to obtain a good understanding of the role played by age- and cause-specific mortality in life expectancy changes between the mid-1980s and the late 1990s in Russia, it is important to analyze separately two major events that affected the country:

- 1984–92: the antialcohol campaign and its reversal,
- 1992–98: the 1992–94 economic and social crisis and the postcrisis period.

First, the gain in life expectancy in Russia (1984–1987) was mainly due to the reduction in deaths from injury and poisoning among young adults (**Figure 5**), directly linked, as we know, to the decline in alcoholism (Shkolnikov and Nemtsov, 1997) and, consequently, to the decline in diseases of the circulatory system, which was closely related to the reduction in alcohol consumption. Indeed the campaign involved a reduction in the state-controlled production and sale of alcohol, an increase in the price of alcoholic drinks, a restriction on private distilling, and the development of specialized medical services. However, all these measures were just a flash in the pan, since they were quickly abandoned.

The second change – the fall in life expectancy observed from 1987 to 1992 – fitted a pattern of age- and cause-specific losses that was highly symmetrical to that of the gains in the preceding period. This is because it was dominated by the rise in deaths from external causes among young adults, reinforced by an increase in mortality from diseases of the circulatory system.

This first large fluctuation, resulting from the antialcohol campaign, did much less to disrupt female mortality than male. Even though the same upheavals as for males can still be observed leading in the same direction for females, they result in only modest effects. The antialcohol policy also had consequences for females, but these were much smaller and somewhat different in nature, since they were almost entirely concentrated on diseases of the circulatory system.

The period that followed saw the decline in life expectancy continue, but with a clearly different dynamic in causes of death – one which contradicts the thesis sometimes put forward that the entire fall in life expectancy in the 1990s can be explained by a simple 'counterselection' phenomenon

Figure 3 Age and cause components of changes in male life expectancy during a period of deterioration and a period of improvement in Poland, Estonia, and Russia.

Figure 4 Age and cause components of changes in female life expectancy during a period of deterioration and a period of improvement in Poland, Estonia, and Russia.

Figure 5 Age and cause components of changes in male life expectancy between 1984 and 1998 in Russia.

(Avdeev et al., 1998; Vishnevskii, 2000). According to this thesis, by leading to an abrupt decline in mortality, the antialcohol campaign delayed the deaths of weaker than average individuals who would otherwise have died. Therefore the population's average state of health deteriorated and, naturally, mortality increased in the years that followed. A cause-specific examination of deaths refutes this thesis in two ways. If it were correct, the rise in mortality immediately following the end of the antialcohol campaign should have resulted from all kinds of causes to which the lives previously saved were more vulnerable. Yet, as we have just seen, this rise was entirely linked to alcohol-related causes (just like the fall in mortality during the campaign). In contrast, from 1992, although mortality had already returned to its precampaign level, the continued rise in mortality resulted from a very different range of causes. Of course, as always in mortality trends for Eastern European countries, the major role played by diseases of the circulatory system and deaths from external causes in the adult age groups is clearly apparent; but these causes did not act alone (all the other groups of causes helped to aggravate the situation) and the losses in life expectancy have an older age profile, even though the fall in infant and child mortality that was also visible in the preceding period gave way to a rise. Far from this new rise in mortality – several years after the end of the antialcohol campaign – being attributable to the deaths of vulnerable individuals temporarily saved by the campaign, it probably relates to a new factor: the economic and social crisis which, at that time, dealt a heavy blow to populations suddenly subjected to the perverse effects of the transition to a market economy, and this blow was the strongest for males

in working ages. After 1995, economic decline continued for a few more years, but at a very reduced pace. Fairly quickly too, after the crisis had passed, the populations involved found the resources to adapt to circumstances, doing more to safeguard their chances of survival. So life expectancy was able to start rising again. In Russia, age- and cause-specific patterns appear almost perfectly symmetrical (Figure 5, lower panel) between the crisis period (1992–94) and the postcrisis period (1994–98).

Like the previous large fluctuation, this second one, linked to the 1992–94 crisis, did much less to disrupt female mortality than male. The sharp movements observed for males produced only modest effects for females, even though still in the same direction. Here too, the really dominant impact was that of diseases of the circulatory system alone, with the effect of deaths from external causes being only secondary in importance (like the other groups of causes).

An Excess Mortality Shifting to Older Ages

Considering long-term trends or fluctuations, it appears that Central and Eastern European women have always done better than men: a less strong worsening, less ample fluctuations, and a more promising trend reversal. These more favorable trends are due to a better health situation at middle ages: women suffered less from alcohol-related mortality and trends in external causes and circulatory diseases were less problematic than for males. In the most recent years, the trend reversal was more driven by progress at older ages, which were more pronounced for women than for men. Does it mean that the difference between Eastern and Western Europe is going to disappear?

Figure 6 displays the age and cause components in the differences in life expectancy between France and Russia, and between France and Poland in 2009 for males and females. The difference appears still very important for males at working

Figure 6 Age and cause components of differences in life expectancy between Russia and France, and between Poland and France in 2009.

ages. For Russia, compared to France, 63% of the total gap (16 years) is due to differences in mortality between age 20 and age 65 and, despite the recent progresses, this part is 48% for Polish males (for a total gap of 7 years with French males). Mortality over age 65 accounts only for 30% of the difference between Russian and French males, and for 48% of that between Polish and French. Even if the recent mortality decrease in Eastern European countries was the most pronounced at relatively young adult ages, there is still a lot to gain at those ages to catch up with Western countries.

On the female side, the situation is altogether different. The gaps in life expectancy observed between Russian and French women (11 years) or between Polish and French women (5.5 years) are mainly related to differences in death rates at older ages (**Figure 6**). Excess mortality over age 65 of Russian females, as compared to French ones, accounts for 57% of the total difference and this part reaches 74% of the French–Polish gap. In the recent years, it is well known that the continuation of life expectancy progress in the most advanced countries was due to a dramatic decrease of mortality at older and older ages (Glei et al., 2010). In that matter, Central and Eastern European countries are far from doing as well as their Western counterparts. In the coming years, it will be a challenging issue for these countries to manage with the health of the elderly population. At age over 85, Russia and Poland females seem to have some advantages for noncirculatory causes of death. Most probably, however, this is only an artifact due to less precise diagnoses among older women. In Eastern European countries, the propensity to attribute deaths at older ages to the circulatory diseases was often stressed. This leads here probably to an overestimation of the part played by circulatory diseases in the difference between East and West, and reversely to the wrong conclusion that Poland and Russia could be in better position for other causes of death. Whatever the differences in the quality of the cause of death statistics, it remains that ages over 85 are now contributing substantially to the differences.

From the mid-1960s, adverse but quite similar mortality trends in Central Europe and the former USSR long contributed to widening the gap between these countries and the rest of Europe. The divergence was mainly due to very different trends in adult mortality at working ages, related to external causes and circulatory diseases. After successfully tackling infectious diseases, industrialized countries had to look for ways of reducing degenerative diseases, and especially circulatory diseases, which were the main factors of mortality, as well as to control behavior-related pathologies (excess alcohol consumption, tobacco smoking). In Western countries, health policies that combined preventative measures with new developments in treatments gradually vanquished these diseases, and their mortality declined substantially. Eastern European countries, by contrast, failed to reverse the increase in circulatory disease mortality that largely contributed to the stagnation or even the decrease of life expectancy (Meslé, 1991; Okolski, 1993; Meslé and Vallin, 2002).

Since the mid-1980s, however, adult mortality trends have developed very differently in Central Europe and the former USSR. Between the late 1980s and the late 1990s, one Central European country after another has reversed long-term negative trends and progress seems well under way, particularly due to a marked decline in mortality from circulatory diseases (Meslé, 2004). Favorable trends, which were observed in Western Europe as long ago as the early 1970s, have now spread to the countries of Central Europe. It is still difficult to assess the main determinants of such a reversal. The progress probably results from the combination of several factors, such as changes in diets, the growth of systematic prevention and screening, the spread of new forms of treatment, and cardiac surgery, in a context of deep reforms of health systems.

At the same time, countries of the former USSR have experienced very marked fluctuations in adult mortality, especially among males, related to the social and economic traumas that these countries have undergone at the end of the twentieth century. After an initial increase in life expectancy following the antialcoholism campaign launched by Gorbachev in 1985, mortality began to rise again as the effects of the campaigns dwindled. The increase accelerated dramatically in 1993–94 when all these countries entered a harsh economic crisis linked to the sudden transition to a market economy. The crisis resulted in a complete dismantling of public services, including the health system, at a time when people were suffering food shortages and psychological stress (Shkolnikov et al., 1998; Gavrilova et al., 2001). Up to the mid-1990s, the trends were completely parallel in all the European republics of the former USSR. From the late 1990s, however, they have begun to diverge. In Baltic countries, mortality trends have more or less mirrored those of Central European countries (Jasilionis et al., 2011). In Russia and Ukraine, the progress was longer to appear. Since the mid-2000s, however, these countries could have also entered a new step of the health transition in succeeding to control alcohol-related pathologies and circulatory diseases (Grigoriev et al., 2014).

If the increase of mortality among young- and middle-age adults was the main factor of the unfavorable trends in life expectancy observed in these different countries, the progress recently observed is driven by a reduction of mortality at all adult ages, including older ages. This phenomenon is especially visible for females. However, when compared to Western countries, the mortality at older ages remains much higher in Central and Eastern Europe. To consolidate the recent favorable trends, the latter need now to take care of the health of their elderly population. As for other advanced countries, this is the main health challenge of the coming years.

Abstract

Adult morality in today's industrialized societies is characterized by steady increases of life expectancy with a tendency toward convergence of mortality levels. Exceptions are countries from Central and Eastern Europe and the Arabian Peninsula. The populations differ more in the causes of death than in the age pattern of mortality changes during the past decades. Women outlive men in all populations. However, differences exist in the time pattern of the sex gap. In general, levels and trends of mortality and sex differences as well as the prevailing driving factors reflect to a large extent the development stages of the populations.

Introduction

In this article, industrialized countries are defined as those nations that were classified as 'high-income economies' by the World Bank in 2013 (See http://data.worldbank.org/about/country-classifications/country-and-lending-groups#OECD_members; accessed on 07.10.13.) and had a population of more than 1 000 000 people on 1 July 2010 according to the 2012 revision of the United Nations World Population Prospects (United Nations, D.o.E.a.S.A., Population Division, 2013). (If not stated otherwise, all figures presented in this article are taken from or calculated from this source.) This selection includes 45 countries with a total of 1.26 billion people in 2010, representing 18.2% of the world population. In the quinquennial 2005–10, 56.5 million deaths occurred in these populations, constituting approximately one-fifth of all deaths worldwide. This at-a-first-glance high proportion is due to the high average age of today's industrialized countries. The proportion of people aged 60 years and older is at 20.8%, almost double that of the total world population (11.1%). This becomes even more apparent when one considers only the population aged 80 years and above. While the proportion of individuals older than 80 years is 1.6% in the entire world population, it is 4.1% in the selected 45 industrialized countries.

Adult mortality is the central factor of current levels and trends of overall survival conditions in today's industrialized countries: In the period 2005–10, 98.8% of all deaths occurred in those aged older than 15 years. In the entire world population, the corresponding proportion is 82.7%. Figure 1(a) shows the age-specific death rates for industrialized countries in comparison to the whole world population in 2005–10. It becomes apparent that the largest differences between industrialized countries and the

Figure 1 Age-specific death rates in different periods, both sexes. Note: Figures for industrialized countries are unweighted averages. Source: United Nations, D.o.E.a.S.A., Population Division, 2013. World Population Prospects: The 2012 Revision, DVD edition. United Nations, New York; and own calculations with data of United Nations, D.o.E.a.S.A., Population Division (2013).

world occur in younger ages. Between birth and the age of 10 years, death rates in industrialized countries are around 90% below the level of the total world. In adult ages this advantage reduces steadily. Between ages 15 and 35, death rates of industrialized populations are between 58 and 66% below the world average; between ages 40 and 65, it is 30–50%; and above the age of 65, the advantage reduces to 10–25%.

In the course of the past 50 years, industrialized countries experienced a continuous decrease of mortality in all ages. This is illustrated in Figure 1(b), which displays the age-specific death rates in today's industrialized countries in the periods 1960–65, 1980–85, and 2005–10. The graph shows further the shift of improvements from younger to older ages. Between 1960–65 and 1980–85, improvements were larger in younger ages, whereas between 1980–85 and 2005–10 stronger improvements occurred in older ages. The following sections provide overviews of the different levels and trends of adult mortality (both sexes combined) in today's industrialized countries and also describe the underlying age- and cause-specific mechanisms and the differences between women and men. The final section summarizes briefly the driving factors of past and current levels of adult mortality and speculates about future trends. More details about regional or country-specific mortality histories and conditions can be found in the *International Handbook of Adult Mortality* (Rogers and Crimmins, 2011).

Current Levels of Adult Mortality

Table 1 summarizes different indicators of adult mortality in today's industrialized countries for the period 2005–10. Remaining life expectancy is given for the ages 15 (e_{15}), 60 (e_{60}), and 80 (e_{80}) years. Additionally, the table includes the survival probabilities from the age of 15 to 60 years ($_{45}l_{15}$) and from the age of 60 to 80 years ($_{20}l_{60}$). The populations are grouped by seven major geographical areas: America (AMA), Northern Europe (NEU), Western Europe (WEU), Central and Eastern Europe (CEE), Southern Europe (SEU), Western Asia (WAS), as well as Oceania, Eastern, and Southeast Asia (OEA). For the entire population of industrialized countries, e_{15} is 63.7 years and thus approximately 5 years higher than in the total world (58.8 years). However, the differences between the individual industrialized countries are still considerable, amounting to almost 15 years. The highest life expectancy at the age of 15 years is reached in Japan (68.0 years), whereas the lowest can be found in the Russian Federation (53.3 years). Even at higher ages the differences in levels of remaining life expectancy are large, amounting to 8.2 years between Japan and the Russian Federation at the age of 60 years and 5.5 years between Japan and Kuwait at the age of 80 years.

The major geographical areas with the largest heterogeneity among industrialized countries in mortality levels are AMA and CEE where e_{15} varies by 9.1 and 8.9 years, respectively. In AMA, the extent of the span is due to Trinidad and Tobago which exhibits the highest mortality levels according to all five mortality indicators. The other countries, including Canada, Chile, Puerto Rico, the United States, and Uruguay, show considerably better and less differentiated mortality conditions, with Canada being the leader in all indicators of adult mortality. Between these five countries, the level of e_{15} varies by 3.3 years. In CEE, the large range is due to the high mortality level of the Russian Federation. The difference from Lithuania, the country with the second lowest level of life expectancy at age 15 in this geographical area, is 3.7 years. The lowest mortality is prevailing in the Czech Republic, where e_{15} reached 62.2 years in the period 2005–10. The Baltic states, Estonia and Latvia, are closer in their mortality levels to Lithuania, whereas Slovakia and Poland are closer to the level of the Czech Republic. Note that Poland has the highest life expectancy at age 80. This indicates that the Polish population exhibits the lowest mortality in highest ages among the industrialized populations of CEE.

The most homogeneous geographical areas of industrialized countries are NEU, WEU, and OEA. Within these regional units, e_{15} varies only by 2.3–2.4 years. The lowest level of mortality is prevalent in OEA where life expectancy ranges between 65.6 years in the Republic of Korea and 68.0 years in Japan. In NEU these values range from 64.0 years in Denmark to 66.4 years in Sweden. The level of e_{15} in WEU lies in between. Belgium stands at the lower end with 65.0 years, and Switzerland exhibits the highest value of 67.3 years. The homogeneity is most distinct in the two European areas, reflected by the fact that the countries with the highest and lowest mortality levels change between the different indicators for adult mortality. In WEU, for instance, Switzerland shares the first rank with France in e_{60} and falls behind the latter in e_{80}. Belgium holds the last place in the rankings only in life expectancy at ages 15 and 60. In e_{80} the Netherlands is at the end of the ranking, in $_{45}l_{15}$ France, and in $_{20}l_{60}$ Germany. In OEA, Japan and the Republic of Korea hold the first and the last place in all but one indicator. In $_{45}l_{15}$, the highest value can be found in Hong Kong and the lowest in New Zealand.

The level of heterogeneity in SEU and WAS ranges between those of the other regions, being 5.2 and 6.4 years in e_{15}, respectively. In the former, the rather large span is due to the relatively high mortality in Croatia with e_{15} being 61.7 years. In all other countries, life expectancy at the age of 15 years ranges between 64.0 (Slovenia) and 66.9 years (Italy). Consequently, Croatia is lowest in the ranking of all presented indicators of adult mortality. At the top, Italy is replaced by Spain as the leader in life expectancy at ages 60 and 80. The countries belonging to WAS are also characterized by very different mortality levels. The division occurs mainly between the populations of the Arabian Peninsula on the one hand with still relatively high mortality and Cyprus and Israel on the other with low mortality. Among the latter e_{15} is at the level of SEU countries, being 64.4 years in Cyprus and 66.3 in Israel. In the industrialized Arab countries Bahrain, Kuwait, Oman, Saudi Arabia, and the United Arab Emirates, e_{15} ranges between 59.9 (Kuwait) and 61.8 years (Bahrain). Qatar stands out as it has reached a life expectancy level between those of the Arab countries and Israel respective Cyprus (63.4 years). Israel and Kuwait are ranked first and last in four of the five indicators for adult mortality. Only in $_{45}l_{15}$ Cyprus performs best and Oman worst.

Table 1 Main indicators for adult mortality (both sexes) in industrialized countries, 2005–10: life expectancy at age 15 (e_{15}), life expectancy at age 60 (e_{60}), life expectancy at age 80 (e_{80}), survival probability from age 15 to 60 in percentage ($_{45}l_{15}$), and survival probability from age 60 to 80 in percentage ($_{20}l_{60}$)

Country-Specific Trends in Adult Mortality

Trends in adult mortality since the mid-twentieth century were characterized by a steady increase of life expectancy in most industrialized countries. These remarkable changes were described intensively during the past decade (Oeppen and Vaupel, 2002; White, 2002; Vallin and Meslé, 2009). Nonetheless, across today's industrialized countries, these trends were heterogeneous and not in every case characterized by a continuous improvement. **Figure 2(a)** illustrates these changes for the eight considered major areas. The most regular trends in e_{15} occurred in OEA and WAS. The trends in NEU, WEU, and SEU are similarly improving since the 1970s, whereas the years before were characterized by stagnating or only mildly improving mortality conditions. AMA differentiates from these areas because improvements since the 1980s lag noticeably. In sharp contrast is the trend in CEE. Between 1950–55 and 1960–65 e_{15} increased as strong as in OEA, followed, however, by a more or less continuous decrease until 2000–05. An interruption of this decline occurred only in the second half of the 1980s when life expectancy increased for some years as consequence of Gorbachev's antialcohol campaign (Murphy, 2011). Whether the increase between 2000–05 and 2005–10 marks a sustained trend change or just another short-term interruption of the long-lasting decrease cannot be assessed to date (see Shkolnikov et al., 2013). The mean annual changes in

Figure 2 Trends in life expectancy at age 15 (e_{15}), both sexes, 1950–2010. Note: Figures of major areas are weighted averages based on the countries' population sizes at ages 15+ in the first year of the 5-year calendar year periods. Figure 2 (*continued*).

e_{15} between 1950–55 and 2005–10 were 0.02 years in CEE, 0.14 in AMA, 0.15 in NEU, 0.16 in WEU, 0.18 in SEU, 0.21 in WAS, and 0.27 in OEA. In relative terms, life expectancy at young adult age increased during the observation time by 2.4% in CEE, 13.7% in AMA, 14.0% in NEU, 15.7% in WEU, 17.8% in SEU, 23.1% in WAS, and 28.2% in OEA.

Figure 2(b) to 2(h) provides more details about the trends in e_{15} for the individual industrialized countries. Countries from SEU, NEU, and WEU are characterized by small differences and very regular trends. Industrialized countries from SEU stand out because they show the most stable trends and differences (Figure 2(b)). In contrast, countries from NEU are characterized by a convergence of mortality levels (Figure 2(c)). Notable are the stalling mortality levels of Norway and Denmark for several decades since the 1950s. While a trend changed toward an increase similar to those in the other countries from NEU occurred in Norway in the second half of the 1980s, this happened in Denmark not before the end of the past millennium.

Industrialized countries in WEU (Figure 2(d)) also appear to converge in levels of life expectancy. However, excluding the Netherlands changes this picture. The Dutch population exhibited by far the lowest mortality levels until the early 1970s. Moreover, the overall trend in the Netherlands looks more similar to those of Norway and Denmark than to that of WEU. Switzerland stands out with the most positive trend as the Swiss population did not experience the stall in life expectancy during the 1960s, which was apparent in all other countries.

Also, the populations belonging to the industrialized countries of the CEE area follow similar trends in e_{15} until the end of the 1980s (Figure 2(e)). Their trends are characterized

by an increase of e_{15} until the mid-1960s and a subsequent decrease until the mid-1980s, which then turned into another increase. Lithuania performed best until the end of this time span and the lowest life expectancy was prevalent in Russia. The fall of the iron curtain divided the populations into two groups. In the Czech Republic, Poland, and Slovakia, the increase of e_{15} – which began in the mid-1980s – continued until the most recent period. In contrast, the countries belonging to the former Soviet Union experienced a further decline in life expectancy. Only recently, Estonia and Latvia experienced an increase of e_{15}, which parallels the trends of the Czech Republic, Poland, and Slovakia.

In AMA (Figure 2(f)), Canada exhibits the lowest mortality throughout the observation period with an almost constant advantage compared to the United States. Puerto Rico reached a similar level of e_{15} in the 1970s but then fell behind until the early 1990s when the trend changed again toward increasing life expectancy. Chile shows the most notable trends. Until the early 1970s, e_{15} was lowest among all industrialized countries in AMA, close to the level of Trinidad and Tobago. From then on, life expectancy increased stronger than in any other population.

Industrialized countries from Asia are also characterized by a strong convergence of life expectancy levels. In WAS, Cyprus had the highest life expectancy until the late 1980s and shows the most constant trend throughout the whole observation period. Qatar, Bahrain, United Arab Emirates, and Saudi Arabia exhibited sharp increases of e_{15} until the 1980s, followed, however, by a noticeable decrease in the pace of mortality improvements. While Qatar was able to reach the life expectancy level of Israel in the 1980s and being still close to Cyprus, there is a notable gap to the other Arab countries. Kuwait started on the same level of e_{15} as Qatar in the early 1950s, but the subsequent increases were smaller in all other countries and life expectancy seems to have stalled in the most recent years. Oman stands out for contrasting reasons as it shows a constant increase of e_{15} until today, however, having the lowest life expectancy until the late 1990s.

Today's industrialized countries from OEA also show heterogeneous but converging trends in life expectancy. Japan, Hong Kong, Singapore, and the Republic of Korea experienced the most regular increases. Korea started with the lowest life expectancy in 1950–55 but approached steadily the level of the other countries. Japan, today's world leader in life expectancy, showed the strongest increases until the mid-1980s when mortality improvements started to proceed with a less marked pace. Life expectancy stalled in Australia and New Zealand until the 1970s, as it can be observed in most other Western societies. Since then, e_{15} increased strongly in Australia, but did less so in New Zealand.

Trends in the Age Pattern of Adult Mortality

The two previous sections were based on the life expectancy at age 15. This indicator summarizes the whole mortality from age 15 onward. Consequently, differences in e_{15} can be caused by very different patterns of age-specific mortality. This section provides more detailed information about these age patterns by subdividing adult mortality into the age segments 15–60, 60–80, and above 80 years. Figure 3 shows for the major areas of industrialized populations the trends in ${}_{45}l_{15}$ (Figure 3(a)), e_{60} (Figure 3(b)), ${}_{20}l_{60}$ (Figure 3(c)), and e_{80} (Figure 3(d)). At a first glance, all displayed trends look similar to those for e_{15} (Figure 2(a)), indicating that the different developments of countries and regions do not reflect significant differences in trends of age-specific mortality.

Within Europe, populations from NEU perform comparatively well in young adulthood, but worse at older ages as reflected in the indicators e_{60}, ${}_{20}l_{60}$, and e_{80}. SEU and WEU are similar in all indicators of adult mortality with SEU showing lower mortality in each of them. CEE performs worse in all indicators, but especially in younger adult ages between 15 and 60 where mortality conditions are deteriorating from the 1960s through at least the early 2000s. In the other age segments, mortality in CEE is rather stagnating than decreasing.

Also, AMA shows the strongest disadvantages in younger adult ages compared to the industrialized populations from the other Western areas. This excess in mortality is apparent throughout the displayed period. In all indicators for mortality from age 60 onward populations from AMA are less disadvantaged, and they exhibited even the lowest mortality until the early 1980s. This becomes most apparent in e_{80} where AMA was around 1 year ahead of populations from Europe. In the most recent period, e_{80} was similar in AMA, WEU, and SEU; in e_{60} and ${}_{20}l_{60}$, AMA is close to the level of NEU.

The pictures for the two Asian areas of industrialized countries are very different compared to the other populations. In WAS, the largest improvements occurred in young adult ages. The mortality levels of AMA were reached during the early 1990s and those of WEU and NEU in 2005–10. In all indictors for mortality above age 60, WAS is lagging behind, and in e_{80}, it lies even below the world average in most of the displayed periods. In contrast, OEA shows strong improvements starting from levels clearly below those of AMA and the European populations and ending at the top position in all indicators. The advantages experienced during the most recent decades are gradually increasing with age and are largest in e_{80}. It appears, however, that the improvements in the highest ages start to slow down since the beginning of the new millennium. It might therefore be that mortality conditions between OEA, NEU, WEU, and SEU will converge during the coming decades. Based on the trends of the past 55 years, this seems not likely for AMA, WAS, and CEE. Note, however, that this applies only to the areas as a whole and does not exclude the fact that some individual countries will remain at or catch up to the low mortality levels apparent in the Western populations of Europe and OEA.

Contribution of the Major Causes of Death to Changes in Adult Mortality

This section further develops the description of differences between industrialized countries. Figure 4 shows age- and cause-specific contributions to the changes in life expectancy at age 15 between 1960–65 and 2005–10 for four selected countries. (The data of this section are taken from the WHO Mortality Database, online available at http://www.who.int/healthinfo/mortality_data/en/; accessed on 20.10.13.)

Figure 3 Trends in the survival probabilities from age 15 to 60 and from age 60 to 80 (in percentage) as well as life expectancy at age 60 (e_{60}) and at age 80 (e_{80}), both sexes, major areas, 1950–2010. Note: Figures of major areas are weighted averages based on the countries' population sizes at ages 15+, 60+, and 80+ in the first year of the 5-year calendar year periods. Source: Own calculations with data of United Nations, D.o.E.a.S.A., Population Division, 2013. World Population Prospects: The 2012 Revision, DVD edition. United Nations, New York.

The gains in e_{15} between 1960–65 and 2005–10 were 12.6 years in Singapore, 8.6 years in Italy, 6.6 years in the United States, and 3.4 years in Poland. These gains are decomposed into the contributions of 5-year age groups between ages 15 and 84 and the group aged older than 85 years. These age-specific contributions are further subdivided into the fractions caused by six major causes of death categories – diseases of the circulatory system, malignant neoplasm, diseases of the respiratory system, diseases of the digestive system, infectious diseases, and external causes of death – and a rest group including all other causes. Naturally, the impact of causes of death on adult mortality differs with age. Since in some cases cause-specific changes were unfavorable, some of the bars lie in the negative area, meaning that these specific causes resulted in a loss of life years between 1960–65 and 2005–10. This is true, for instance, for malignant neoplasms in the highest ages in all displayed populations.

Figure 4 reveals some similarities as well as significant differences in the age- and cause-specific changes in adult mortality in the four displayed populations. All have in common the fact that the largest contributions to gains in e_{15} originate close to the retirement age. The modes are located at age 60–64 in Singapore, 65–69 in the United States, 70–74 in Poland, and 75–79 in Italy. The smallest contributions come from the ages 15–49, which caused e_{15} to increase between 1960–65 and 2005–10 by 0.8 years in Poland (23.5% of the total increase in e_{15}), 1.1 years in the United States (16.6%), 1.6 years in Italy (18.6%), and 2.5 years in Singapore (19.8%).

Figure 4 Age- and cause-specific contributions to changes in life expectancy at age 15 (e_{15}) between 1960–65 and 2005–10 and major causes of death, selected countries. Source: Own calculations with data of WHO Mortality Database.

The most regular age pattern in contributions to the gain in e_{15} is prevalent in Italy with a steady increase until the mode and an incremental decrease thereafter. In the United States and Singapore, the group aged older than 85 years contributed stronger than that aged 80–84 years. Poland differs strongest from the others, reflecting to some extent the typical Eastern European pattern of adult mortality. This is characterized by high and stagnating – in some countries even increasing – mortality in some age groups.

In general, the cause of death patterns of mortality changes differ more notably between the four populations than the age patterns. In the United States, the 6.6 years gain in e_{15} between

1960–65 and 2005–10 was mainly due to diseases of the circulatory system (4.8 years or 72.9%). Malignant neoplasms contributed 0.5 years (7.3%), external causes of death 0.3 years (4.9%), diseases of the digestive system 0.3 years (4.4%), and other medical causes 0.8 years (12.6%). The positive and negative contributions of diseases of the respiratory system canceled each other out, and infectious diseases caused a slight decrease of e_{15} amounting to 0.2 years (−2.2%). In Singapore, all cause of death categories contributed positively to the 12.6 years gain in e_{15}: diseases of the circulatory system 2.4 years (19.0%), infectious diseases 1.4 years (11.4%), diseases of the respiratory system 1.2 years (9.7%), malignant neoplasms 1.1 years (8.5%), external causes 0.6 years (4.7%), and diseases of the digestive system 0.5 years (4.2%). The largest contribution originates by the sum of all other medical causes, which contributed 5.4 years (42.5%) to the increases in e_{15}.

It is important to note that this rest category contains ill-defined deaths and thus some part of the other medical causes would belong actually to the main cause of death categories. Ill-defined deaths have several reasons, which hampers the comparability of international comparisons and their extent reflects the quality of the statistical systems (Mathers et al., 2005). The Italian registration system seems therefore less deficient as other causes of death contributed only 25.2% (2.2 years) to the gains of young adults' life expectancy. Diseases of the circulatory system contributed 3.6 years (42.3%) to the total gain in e_{15} of 8.6 years, diseases of the respiratory system 0.8 years (8.7%), diseases of the digestive system 0.7 years (7.6%), external causes 0.6 years (6.8%), malignant neoplasms 0.6 years (6.6%), and infectious diseases 0.2 years (2.8%). Thus, in Italy also all cause of death categories contributed positively to the changes in e_{15}. This is not the case in Poland where malignant neoplasms reduced life expectancy by 0.5 years (13.7%). Also, diseases of the digestive system caused e_{15} to decrease slightly by 0.02 years (0.6%). The increase of e_{15} by 3.4 years between 1960–65 and 2005–10 was mainly due to the sum of other medical causes containing ill-defined deaths (2.4 years or 71.8%). Improvements in infectious diseases increased e_{15} by 0.8 years (24.9%), diseases of the circulatory system by 0.4 years (11.6%), and diseases of the respiratory system and external causes each by 0.1 years (3.7 and 2.4%, respectively).

Trends and Patterns of Sex Differences in Adult Mortality

All previous sections analyzed mortality conditions and trends for total populations without separating by sex. However, women and men of industrialized populations differ significantly in life expectancy as well as age-specific mortality. Across the populations of today's industrialized countries, women's life expectancy at age 15 exceeded those of men by 6.4 years in 2005–10. The sex differences vary greatly between countries, ranging from 1.3 years in Bahrain to 12.6 years in Russia. Figure 5(a) shows the trends of female–male differences in e_{15} for the major areas of industrialized countries and the entire world population from 1950–55 to 2005–10. Most of these area groups exhibit the basic pattern of a reversed U-shape with a regular increase of sex differences until a turning point from when on the differences decrease in a similar steady manner. The trend reversal occurred first in AMA and NEU at the end of the 1970s, followed by SEU and WEU at the end of the 1990s, and then in OEA and CEE at the beginning of the new millennium. In the OEA and CEE, the trend of increasing sex

Figure 5 Trends in sex differences in life expectancy at age 15 (e_{15}) and at age 80 (e_{80}), 1950–2010. Note: Figures of major areas are weighted averages based on the countries' population sizes at ages 15+ and 80+ in the first year of the 5-year calendar year periods. Source: Own calculations with data of United Nations, D.o.E.a.S.A., Population Division, 2013. World Population Prospects: The 2012 Revision, DVD edition. United Nations, New York.

differences was shortly interrupted during the late 1980s when the gap decreased as a consequence of periodically decreasing – mainly male – mortality due to external causes of death (Leon et al., 1997). In WAS, sex differences in e_{15} increased only marginal throughout the displayed period without any change in the basic trend. The sex gap was 2.8 years in 1950–55 and 3.2 years in 2005–10.

More notable than the differences in the trend are the differences in the extent of the sex gap in life expectancy. The smallest gap in e_{15} is apparent in WAS. In contrast, male excess mortality is largest in CEE where women outlived men by 7.0 years in 1950–55 and 11.4 years in 2005–10. The other areas lie between these extremes and show less differences in the extent of the sex gap. From the 1950s until the early 1980s, sex differences were higher in AMA than in the Western European populations and OEA. In 2005–10, OEA shows the highest differences of these areas as a consequence of the late peak in the trend of the sex gap.

With regard to e_{80} there are two notable differences (see **Figure 5(b)**). The first concerns CEE where the male disadvantage is much smaller. Since the late 1970s, sex differences in e_{80} are even the lowest among the European areas, being on the level of sex differences of the total world population. This reveals that the extraordinary high male excess mortality in e_{15} is predominantly caused by the high mortality of men in young and middle adult ages. The second significant difference between sex differences in young and old adult ages is prevailing in OEA where the recently observable trend reversal in e_{15} is not visible in e_{80}. In contrast, sex differences at highest ages are sharply increasing even in the most recent observation period.

Within the major areas, the individual industrialized populations show similar trends in the sex gap in e_{15} (data not shown, but available on request from the author). AMA is characterized by a difference between populations from North and South America with the trend change occurring later in the latter. In 2005–10, the sex gap in e_{15} ranged between 4.6 years in Canada and 7.9 years in Puerto Rico. In CEE, the former member states of the Soviet Union show identical 'roller-coaster' trends with similar extents of the sex gap, while sex differences in the populations from Central Europe follow a regular pattern with the peak occurring in the early 1990s. Among these populations, the lowest gap is currently apparent in the Czech Republic with a female surplus of 6.2 years. The single Western European countries follow basically the trends of the defined geographical areas. In the most recent period, 2005–10, sex differences in e_{15} range in WEU from 4.1 years in the Netherlands to 6.9 years in France, in SEU from 5.0 years in Greece to 7.0 years in Slovenia, and in NEU from 4.1 years in Sweden to 6.8 years in Finland.

The areas OEA and WAS show the most heterogeneous trends between countries. Australia, New Zealand, and the Republic of Korea exhibit trends in the sex gap similar to the Western populations of Europe and AMA with the peak occurring in the late 1970s and the early 1980s. However, the extents differ markedly. In 1950–55, sex differences in e_{15} were 3.1 years in the Republic of Korea, 3.9 years in New Zealand, and 5.1 years in Australia. At the time of the peak, the differences amounted to 6.2 years in New Zealand, 6.8 years in Australia, and 8.8 years in the Republic of Korea. Until 2005–10, the sex gap decreased to 4.0 years in New Zealand, 4.4 years in Australia, and 6.7 years in the Republic of Korea. In Japan, sex differences increased continuously until the beginning of the new millennium and started to decrease just recently. The gap was 3.3 years in 1950–55, 6.9 years in 2000–05, and 6.8 years in 2005–10. Very different patterns are apparent in Hong Kong and Singapore. While the former shows the reversed Japanese pattern with the sex difference being 7.4 years in 1950–55, 5.7 years in 2000–05, and 6.1 years in 2005–10, the sex gap developed irregularly in the latter. The female surplus in e_{15} increased from 5.6 years in 1950–55 to 6.3 years 1970–75, then decreased to 4.3 years in 1985–90, and finally increased again to 5.0 years in 2000–05 and 2005–10.

Populations from WAS show even stronger differences in trends of the sex gap. In Saudi Arabia and Cyprus, sex differences in e_{15} increased constantly but slowly from 3.1 and 3.9 years in 1950–55 to 3.5 and 4.1 years in 2005–10, respectively. Israel and Oman exhibit constant but strong increases from 1.4 and 2.3 years in 1950–55, respectively, to 4.0 years in 2000–05. While in Israel the sex gap decreased in the subsequent quinquennial 2005–10 to 3.9 years, it increased further in Oman to 4.2 years. In Kuwait, the sex gap increased between 1950–55 and 1970–75 from 2.0 to 2.5 years, then decreased to 1.7 years in 1990–95 from when on it remained constant until 2005–10. In the remaining countries, the trends in sex differences are characterized by a strong decrease over the observation period. In Bahrain, the female advantage in e_{15} decreased steadily from 4.5 years in 1950–55 to 1.3 years in 2005–10; in the United Arab Emirates, it decreased over the same time from 4.0 to 1.8 years with a recent leveling off tendency; and in Qatar, sex differences decreased from 4.1 years in 1950–55 to 1.2 years in 1985–89, and then they increased again to 1.7 years in 2005–10.

Driving Factors of Past Trends in Adult Mortality and Expectations for the Future

The descriptive comparative trends presented for adult mortality in today's industrialized populations are illustrative. This last section summarizes an overview of driving factors of trends in mortality in low-mortality countries elaborated by Caselli et al. (2014) where more details can be found. Generally spoken, levels and trends of mortality in today's industrialized populations as well as the prevailing driving factors reflect to a large extent the development stages of the populations. For the early developed populations from North America, Oceania, and Europe, trends in life expectancy for the overall and sex-specific populations are most likely due to health behaviors (predominantly tobacco consumption and – above all in CEE – alcohol consumption and violence), health conditions (especially obesity), and structural factors including socioeconomic position, health care access, and health insurance. For instance, compared with Canada, the United States has higher prevalence rates of smoking, obesity, and violence, along with limited access to health care. Moreover, the United States has had a longer history of cigarette consumption, especially among men, which has contributed to lower male life expectancies and larger sex gaps compared with Canada (Pampel, 2005). Smoking-related mortality has also

been shown to be responsible for the less favorable developments in life expectancy in Denmark, the Netherlands, and the United States (Christensen et al., 2010; Preston et al., 2009).

It has been demonstrated that the trend in smoking prevalence follows the spread pattern of an epidemic and involves a diffusion process across socioeconomic strata (Lopez et al., 1994). Smoking starts among groups of high socioeconomic status and then spreads to the rest of the population. Similarly, the decline in smoking prevalence begins among groups of high socioeconomic status, who are typically the first to become concerned with the harmful effects of smoking. These processes can be observed among both sexes, with higher prevalence rates in men and a time lag of two to three decades between men and women. Although the early developed populations are today in later stages of the smoking epidemic, they are still not at the end of this process (Ng et al., 2014). Thus, future trends in life expectancy are likely to be determined by trends in tobacco consumption. For instance, Wang and Preston (2009) predicted for the US population that the changes toward lower smoking prevalence will lead to a faster mortality decline than anticipated by most experts (see also Bongaarts, 2006; King and Soneji, 2011). In many industrialized countries, national health policies are currently conducting intensive antismoking campaigns. Evidence suggests that these measures are effective and thus can be expected to lead to further decreases of smoking rates (e.g., Ádám et al., 2012). The later developed populations among today's industrialized countries are still in earlier stages of the smoking epidemic. It is therefore possible that their future trends in adult mortality will be influenced by increasing smoking prevalence for some decades as observed in the earlier developed populations among men until the 1980s and among women in the more recent past.

Nonetheless, smoking might be the most important driver of recent trends in adult mortality, but its impact differs between populations and it is not the only factor with significant impact on life expectancy levels. How these factors are linked with each other and how they will influence future mortality is heavily debated among demographers, epidemiologists, and researchers from other public health areas. In recent years, two schools of thought have developed that dominate the discussion about the most likely trends of future life expectancy whose supporters are generally referred to as 'optimists' and 'pessimists' (for the most recent dispute see Olshansky and Carnes, 2013; Vaupel and Rau, 2013). Both agree that mortality will continue to decrease, lifespan will increase, and life expectancy records will continue to be broken. Thus, the difference of opinion between the two schools about likely future trends in life expectancy is in fact smaller than generally presumed (Bongaarts, 2006; Wilmoth, 2001). They differ, however, in their expectations regarding the time course and magnitude of these improvements. Today, the majority of researchers tend to follow the optimistic perspective along with the expectation that the still existing differences in mortality between countries are likely to narrow further in the future (see Caselli et al., 2014).

Abstract

Dependency means the ongoing need for external support, but also reflects, to a lesser extent, affiliation, attachment, and bonding to significant others. Autonomy can be defined as a state in which the person is, or feels, capable of pursuing life goals by use of his or her own resources. Based on these definitions, this article discusses the complexities inherent to these terms. Considerations of developmental tasks in middle adulthood lead to the insight that dependency and autonomy normally have fused into interdependence in this life period. Distinctions between structured, physical, and behavioral dependency are used to address the dependency–autonomy dialectic in old age. New research challenges are finally addressed.

Dependency strictly means the ongoing need for external support (e.g., from family members, professionals, state institutions, intensive care units, or assistive devices) in order to fulfill individual or societal expectations regarding what is a 'normal' life. A less strict interpretation of dependency also encompasses human needs for affiliation, attachment, and bonding to significant others, such as to one's partner, children, grandchildren, or close friends (Baltes and Silverberg, 1994). Autonomy can be defined as "a state in which the person is, or feels, capable of pursuing life goals by the use of his or her own resources" (Parmelee and Lawton, 1990: p. 465). Autonomy thus means independent and effective functioning in a variety of life domains ranging from basic activities of daily living to expanded leisure activities, and complex decision-making processes. Constructs related to autonomy are *environmental mastery*, a term suggested by Ryff (1989) as an indication of successful aging, having the feeling that one is the origin of one's own actions (frequently referred to as *primary control*, e.g., Heckhausen et al., 2010), or possessing *self-efficacy* (Bandura, 1977).

Historically, developmental researchers have primarily examined the dynamics between dependency and autonomy from childhood to adolescence. In old age, dependency and loss of autonomy were long viewed as direct consequences of aging worthy of systematic description (e.g., in epidemiological studies) but basically inevitable and irrevocable. It was only in the 1970s that new research findings – based on a more optimistic image of old age and stimulated by a social learning perspective – demonstrated the plasticity of dependency and autonomy in old age (Baltes, 1973). While research in the 1980s and 1990s significantly furthered this insight, middle adulthood, and also the transitions in dependency and autonomy that are experienced as the adult individual matures, attracted so far little scientific interest (Willis and Reid, 1999).

On the Complexities of Dependency and Autonomy in Adult Life

From a life-span perspective, childhood and adolescence are periods when striving toward autonomy and reducing dependency are among the most important *developmental tasks* (Havighurst, 1972). By young adulthood, or at the very latest by middle adulthood, one is normally expected to have accomplished this successfully. Conversely, old age may be characterized, at least to some extent, as a life period that poses the risk of becoming dependent or losing one's autonomy. However, the general assumption that autonomy gradually replaces dependency and then dependency gradually replaces autonomy over the life course is clearly simplistic.

Cultural relativity becomes particularly obvious in the autonomy–dependency dynamics across the life span. For example, while the developmental goal of maintaining autonomy in a wide variety of life domains over the life span is one of the highest values in most Western cultures, one of the most 'normal' elements of many developing countries' or Asian cultures is reliance on children in the later phases of life. Second, although autonomy and dependency play their roles as individual attributes, both should be regarded predominantly as contextual constructs depending strongly on situational options and constraints. For example, the dependent self-care behavior of an 85-year-old man or woman may not reflect physical or mental frailty at all, but may primarily result from the overprotective behavior of family members and professionals (Baltes, 1996). Third, autonomy and dependency should both be regarded as multidimensional, that is, gain in autonomy in one life domain does not automatically lead to reduced dependency in other life domains and vice versa. For example, being able to meet the everyday challenges of life in an independent manner does not necessarily prevent a younger individual from relying strongly on parents or significant others when making a crucial life decision (such as selecting a partner). Fourth, and finally, autonomy and dependency have strong value connotations which shape action. In Western cultures, independent behaviors are generally regarded as positive and highly adaptive, worth supporting by all means, whereas dependency has negative value connotations and should be avoided at all costs. Such global value attributions can be questioned in terms of life complexity and richness. For example, emotional dependency upon another person lies at the heart of mature intimate relationships and may indeed be seen as an important developmental gain associated with aging. Laura Carstensen (2006) argues in her socioemotional selectivity theory that as we move along the life span, we

increasingly invest into bonding processes with intimate others and that such behavior echoes an important motivational shift in the second as compared to the first half of life. Conversely, striving for autonomy may become detrimental when confronted with severe chronic illness, which necessitates help, support, and the delegation of control to the external environment. These differentiations have to be kept in mind as we examine autonomy and dependency in middle and old age more closely.

Dependency and Autonomy – A Challenge in Midlife?

Answers to this question must start with the developmental challenges associated with the life phase that occurs between roughly 45 and 65 years of age. According to life-span theorist Erik Erikson (1950), one central challenge of human midlife is *generativity*, that is, support of and solidarity with the following generations not only in terms of concrete child-rearing activities, but also in the broader sense of transfer of one's own life expertise and experiences to others. Coping with the 'empty nest,' establishing bonds to grown-up children, and becoming a grandparent are other typical challenges to be met in this life phase. With respect to women, the experience of menopause is the most typically age-graded event in this life period, while one of the most challenging nonnormative events of modern middle-aged women (very much less so for men) is taking over the care-giving role for one's father or mother.

What kinds of implications do these midlife challenges have with respect to autonomy and dependency? As Baltes and Silverberg (1994) have persuasively argued, the term *interdependence* best encompasses agency and autonomy *and* attachment and bonding needs in the middle years. Interdependence typically is at work in generativity, where the older generation is dependent on the younger generation in order to feel needed (particularly after children have left home). Generativity particularly means the strong motivation of older adults to teach and mentor younger generations (Erikson, 1950). At the same time, interdependence can strengthen feelings of agency, competence, and autonomy by providing a forum for the transfer of advice, expertise, and 'world knowledge.' The new role of being a grandfather or grandmother further adds to interdependence, particularly in women. As has been argued (Hagestad, 1985), women more easily express interdependence and attachment and thus contribute more to the maintenance of family and kinship. Furthermore, interdependence finds expression in social relations in midlife by helping others and receiving help, i.e., by mutuality and reciprocity, thus contributing to the establishment of a *social convoy* which guarantees social support throughout life (Antonucci, 2001). However, providing care for a chronically ill parent may also negatively impact on well-balanced interdependence: the moral obligation to care for a family member, and also the loss of autonomy one endures in order to provide such care, can lead to severe psychological distress in midlife (Pinquart and Sörensen, 2003).

Driven by the idea of developmental tasks (Havighurst, 1972), autonomy issues in midlife also crystallize in major decision-making processes. One such critical decision important for future personal development is when and how the retirement process is initiated (Löckenhoff, 2012). As has been found, autonomously facing and preparing this decision in a timely manner seems to be associated with how people later adapt to the postretirement phase.

On the Many Faces of Dependency and Autonomy in Old Age

With respect to later life, Margret M. Baltes (1996) has introduced distinctions among structured, physical, and behavioral dependency. *Structured dependency* implies that human worth is determined primarily by participation in the labor force. According to this understanding, society is in a sense producing dependency among certain subgroups (such as the aged) in order to provide opportunity structures for other subgroups (such as younger persons). *Physical dependency* is closely linked to the age-related emergence of chronic physical and mental impairments such as severe mobility loss or Alzheimer's disease. *Behavioral dependency* primarily reflects the effect of the interaction between the older person and his/her social environment, thus emphasizing most strongly of all three forms of dependency, the role of social and behavioral processes in order to explain dependency in the later years. Owing to the understanding of dependency in social and behavioral terms, a whole empirical research program has been conducted by M. Baltes and associates (for an overview, see Baltes, 1996). The major and very robust finding was that social interactions between older adults and social partners are prone to a *dependence–support script*, that is, dependent behavior among elders is reinforced by their social partners (typically by direct helping behavior), whereas autonomous behaviors are typically ignored.

Furthermore, structured, physical, and behavioral dependency interact with each other, that is, macro-social, biological, and psychological processes must be considered in conjunction. Three theoretical approaches have been discussed to address this dynamic interplay and its outcomes. First, dependency in old age may be due in part to *learned helplessness*, that is, an existing noncontingency between action goals and consequences (Seligman, 1975). Macro-social (see again the term structured dependency) and noncontrollable biological impairments may contribute to dependency in this vein. Second, dependency may also be interpreted as a strong instrument for *passive control*. In this regard, the dependence–support script found in the Baltes research also reflects the power of dependent behaviors of elders to provoke positive responses (typically help) from their social environment and thus maintain environmental control as long as possible. The adaptational value of this strategy is particularly suggested by the *life-span theory of control* (Heckhausen et al., 2010). Third, an even more complex interpretation of the dynamics between dependency and autonomy in old age comes into the play when adaptation and the striving for a successful course of aging are viewed in terms of *selective optimization with compensation* (Baltes et al., 2006). In this respect, dependent behaviors in certain life areas (such as basic care needs) may be seen as a powerful compensation tool in the late phase of the human life span in order to prepare the field for further optimization and

development in selected other life domains with high personal priority.

In addition, as seen from a personality developmental view, findings from now available longitudinal research support the view that it would be an oversimplification to assume that dependency is decreasing in all respects. As has for instance been found, dependency-related modes of coping (such as displacement and regression) are decreasing with age, while autonomy related modes (such as intellectualization) are indeed increasing (Diehl et al., 2014). In a sense, thus, although bodily strengths and biological functioning are clearly on the fall as we age, more inner-psychic forms of autonomy may increase. This is also echoed in classic theories of life-span development, such as in Erikson's (1950) concept of ego–integrity in old age as well as more recently in the theory of gerotranscendence (Tornstam, 2005).

Among the major threats of autonomy in old and very old age are dementia-related disorders, that is, pathological impairment of cognitive abilities and the human capacity to exert executive control (Wettstein et al., 2012). In fact, losing one's autonomy in physical and mental functioning and becoming strongly dependent on others is the behavioral core of dementia. But even regarding normative cognitive development in later life, it is important to note that cognitive performance is among the major predictors of autonomous functioning in everyday life (Diehl and Willis, 2004). It is also noteworthy that keeping autonomy in basic activities of daily life (e.g., self-care, meal preparing) is predominantly associated with physical and cognitive functioning, whereas autonomy in expanded activities (e.g., cultural and educational activities, social activities) is more strongly related with personality differences (Baltes et al., 1999). Another major threat to autonomy in later life is chronic vision impairment, affecting about 20% of those who are 65 years and older and about 30% of those who are 80 years and older (Wahl, 2013).

Among the important decisions to be made in old age are residential decisions. Residential decisions are closely interrelated with autonomy and dependency, because different forms of living arrangements may very differently impact on autonomy and dependency. For example, deciding to invest into one's apartment/house in terms of home modification may significantly extend the time period to 'age in place' (Wahl et al., 2009). Aging in place at the same time is a major symbolic clue for many older adults that they 'still' are autonomously operating individuals. On the other hand, moving to a long-term care institution may at the first glance speak to giving up autonomy and risk dependency, but may also echo an important selection, compensation, and optimization strategy with the potential to unfold new developmental pathways for an aging individual (Baltes et al., 2006).

Overall, it seems to be among the major challenges of old and very old people to deal with an ongoing *dialectic* between autonomy and dependency. On the one hand, important resources to maintain autonomy, such as physical functioning, are shrinking in old age, while others operating more in the inner-psychic domain are indeed possibly increasing. At the same time, older adults are becoming more dependent on others, but part of such dependency, e.g., in the emotional realm, seems to be highly adaptive. Such a view is also supported by findings of the Berlin Aging Study that inform the view that the human phase of very old age is characterized by relatively stable maintaining of internal control, while increase in external control beliefs has been observed in parallel (Smith and Baltes, 1999).

In terms of cohort dynamics and new developments, it is also interesting to see that the concepts of autonomy and dependency may find new variations. For example, technology such as the Internet and robotics increasingly is serving older adults toward maintaining their autonomy and indeed a new understanding of what it means to be autonomous may appear based on the role which technology is going to play in future aging (Wahl et al., 2012). At the same time, such increase in the use of technology may also lead to new forms of dependency, for example, when technology fails and by this means elicits new risks.

Conclusions and New Research Directions

The dynamic interplay between dependency and autonomy occurs in different variations across the adult human life span. While the creation and regulation of interdependence is among the major tasks of middle adulthood, the particularities of old age call for the consideration of different pathways to explain the etiology and maintenance of dependency in old age. The insight of the behavioral model of dependency, pointing to the different roles that dependency can take as an adaptive tool in old age, also means a challenge for intervention. Owing to the potential role of dependent behaviors for successful aging, intervention efforts should always be framed within a change philosophy that leaves the older person in control of whether external autonomy-enhancing efforts should be exerted or not. Autonomy in old age, in this sense, may also mean the autonomy to decide for dependence in some life domains, even if this might mean the risk of losing available competencies in the long run by *disuse*.

New research directions should follow at least four avenues. First, research should examine forms of interdependency in midlife, with a view to understanding how they affect dependency in old age. Second, the interaction between social and physical environmental influences and personality traits, and also their effect on fostering dependency or maintaining autonomy, deserves more consideration. Third, more knowledge is needed on the day-to-day balancing and rebalancing of dependency and autonomy and their emotional and behavioral outcomes. For this kind of empirical research, the model of selective optimization with compensation (SOK; e.g., Baltes et al., 2006) and the life-span theory of control (Heckhausen et al., 2010) are probably the best theoretical alternatives to date. The SOK model assumes that an important process of developmental regulation is selection; in addition, compensation is needed in case of reduced competencies and blocked goals. If selection and compensation are orchestrated well, then also optimization is possible at any stage of the life span. The life-span theory of control assumes that more secondary control execution, i.e., compensatory control processes such as replacing no longer achievable goals, is adaptive as we age. Fourth, exploring new forms of autonomy and dependency, particularly those

connected with technology, is an intriguing future research area (Wahl et al., 2012).

Adverbial Clauses

Jingxia Lin, Nanyang Technological University, Singapore

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by B. Kortmann, volume 1, pp. 162–167, © 2001, Elsevier Ltd.

Abstract

Adverbial clauses are known from traditional grammar as one of three major classes of subordinate clauses. They are semantically diverse and structurally complex. In addition to modifying main clauses, adverbial clauses can also contribute to discourse cohesion. In light of recent cross-linguistic research, this article discusses adverbial clauses with regard to their structure and distribution, meanings, functions in discourse, and structural properties influencing their interpretation.

Adverbial clauses are known from traditional grammar as one of three major classes of subordinate clauses (the other two being relative and complement clauses). Their major function is that of an adverbial, i.e., they provide information on the (temporal, locative, causal, conditional, etc.) circumstances under which the events depicted in the main clauses take place. Correspondingly, the adverbial clauses in (1) are called temporal, locative, causal, and conditional clauses, respectively.

1. They will meet…
   a. before the sun rises.
   b. where they first made love to each other.
   c. because they need to find a solution.
   d. if we let them.

Given the large spectrum of possible circumstances, adverbial clauses represent the most semantically diverse class of subordinate clauses as well as the most challenging class for interpretation. Also given their subject-predicate structure, adverbial clauses are formally the most complex type of adverbials compared with adverbs (e.g., soon, here, quickly) and adverb phrases (e.g., on Sunday, in the garden, very quickly). Combining with a sentence frame like 'They will meet …' in (1), adverbial clauses yield a complex sentence, whereas adverbs and adverbial phrases still yield a simple(x) sentence. Beyond the complex sentence of which they form a part, adverbial clauses have a crucial function in the creation of a coherent discourse and are thus a prominent feature of texts. It seems that adverbial clauses can be found in all languages of the world even though they are not marked in the same way (Thompson and Longacre, 1985). In light of recent cross-linguistic research, this article discusses adverbial clauses with regard to their structure and distribution (Section The Structure and Distribution of Adverbial Clauses), meanings (Section Semantic Types of Adverbial Clause), functions in discourse (Section Functions of Adverbial Clauses in Discourse), and structural properties influencing their interpretation (Section The Interpretation of Adverbial Clauses).

The Structure and Distribution of Adverbial Clauses

The Structure of Adverbial Clauses

Adverbial clauses are subordinate clauses in the sense that their occurrence usually depends on the main clause. However, not all languages mark the distinction between dependent and independent clauses in the same way. Here are the devices that are commonly found among languages: (i) adverbial subordinators, either in the form of separate words such as 'before' and 'where' in English (1) or verbal suffixes as in Kiowa (a language in central United States) (2); (ii) special verb forms such as infinitives and participles as in English and Latin (3); (iii) special word order as in German where independent clauses usually uses verb-second word order whereas subordinate clauses usually use verb-final word order (4) (Dryer, 2011; Thompson et al., 2007).

2. à-dę̀·k'ɔ́··àl hɔ́n àn à-dę̀·hę̀·m-ô
   1SG-lie-although NEG HAB 1SG-sleep-NEG
   "Although I lie down, I can't fall asleep." (Dryer, 2011 from Watkins, 1984: 242)
3. Inflating her lungs, Fiona screamed.
4. Wir wohn-ten auf dem Lande,wie ich dir schon gesagt habe
   we live-PAST on ART(DAT) land as I you already told have(SG)
   "We lived in the country, as I have already told you." (Thompson et al., 2007: 239)

Adverbial clauses may also be expressed in verbless form, as the English example in (5). Such clauses typically do not specify in which way (temporally, causally, conditionally, etc.) they modify the state of affairs described in the main clause and thus are much more challenging for interpretation than most prototypical adverbial clauses.

5. Alone in his room, she switched on the light.

Subordinators in the form of separate words (such as 'that' and 'if' in English) are the most common way to mark adverbial clauses (Dryer, 2011). Yet the presence of a subordinator does not guarantee that the relevant subordinate clause can be classified as an adverbial clause or a relative or complement clause. As illustrated in (6), the word 'that' is used as an adverbial subordinator in (6a), but a complementizer in (6b) and a relativizer in (6c):

6. a. He talked so fast that most people couldn't follow.
   b. He said that most people couldn't follow.
   c. The talk that most people couldn't follow was given by a colleague of mine.

The sentences in (6) show that even in individual languages there may exist no formal differences between the three major types of subordinate clause. Rather, we need to refer to their

function to determine the type: an adverbial clause is a modifier of the main clause and thus optional; a relative clause is a modifier of a noun (phrase) and thus optional; a complement clause is the core argument of a predicate and thus not omissible (Diessel, 2001).

Even though, a clear-cut classification may still be impossible or depend on one's point of view. The subordinate clauses in example (7) are sometimes called adverbial relative clauses since they "can be paraphrased with a relative clause with a generic and relatively semantically empty head noun" (Thompson et al., 2007: 245); in other words, 'when,' 'where,' and 'as' in (7) can be analyzed as relative adverbs rather than adverbial subordinators and replaced by 'at the time,' 'at the place,' and 'in the way,' respectively. As a matter of fact, it is not difficult to find languages where in particular adverbial clauses of Time, Place, and Manner resemble and share properties with relative clauses (Kortmann, 1997; Diessel, 2001; Thompson et al., 2007).

7. a. She'll leave when John comes.
   b. I forgot the bag where we met last time.
   c. He wrote as his teacher taught him.

The Distribution of Adverbial Coordinators

Adverbial subordinators, by which adverbial clauses are morphologically marked, have two major forms: separate words and verbal suffixes. According to the investigation of 660 languages by Dryer (2011), adverbial subordinators in the form of separate words have three possible positions in a clause, at the beginning as in English, at the end as in Kombai (a Trans-New Guinea language in Indonesia), or inside the clause (e.g., between the subject and the verb) as in Nkore-Kiga (a Bantu language in Uganda); adverbial subordinators in the form of verbal suffixes are mostly found in verb-final languages, so the suffixes are also at the end of the clause (in such cases, the adverbial clause usually precedes the main clause), so that the suffix subordinator is not sentence-final (see Section The Ordering of Adverbial Clauses and Main Clauses).

The number of languages whose adverbial clauses are marked by separate words is much larger than those by verbal suffixes; among the former, the number of languages with clause-initial adverbial subordinators is about four times larger than those with clause-final and clause-internal subordinators (Dryer, 2011). There are also languages with more than one type of subordinators and none of them is the dominant; for instance, the adverbial subordinators in Epena Pedee, a Choco language in Colombia, are found both in words (in clause-final position) and verbal suffixes (Dryer, 2011). However, no language is found yet where its adverbial clauses are marked by verbal prefix.

The Ordering of Adverbial Clauses and Main Clauses

Adverbial clauses either precede or follow the main clauses and are referred respectively as preposed (or initial) and post-posed (or final) adverbial clauses. Studies found that preposed adverbial clauses tend to occur in strong OV languages, so that the sentence ends with the main clause; VO languages and a small number of OV languages are found with both pre- and post-posed adverbial clauses (Diessel, 2001, 2013). The ordering of the adverbial and main clauses also correlates with the position of the adverbial subordinators described in Section The Distribution of Adverbial Coordinators: languages with both pre- and post-posed adverbial clauses tend to have clause-initial subordinators, whereas languages with preposed adverbial clauses only tend to have clause-final subordinators (Diessel, 2001; Thompson et al., 2007). For the former type, studies show that the ordering of the adverbial clauses varies according to their semantic relations with the main clauses: conditional clauses tend to be preposed, temporal clauses exhibit a mixed tendency of both pre- and post-posing, whereas causal and purposive clauses are often found to follow the main clause (Diessel, 2001, 2008, 2013; Diessel and Hetterle, 2011; Schmidtke-Bode, 2009). Pre- and post-posed adverbial clauses also tend to have different pragmatic functions in discourse (see details in Section Functions of Adverbial Clauses in Discourse).

The relations of pre- and post-posed adverbial clauses to the main clauses are not the same either. For example, in interrogative questions, the information carried in a post-posed adverbial clause is usually included in the question, but that in a preposed one is usually not (Diessel, 2013). As illustrated in (8), the post-posed adverbial clause 'while she was still in her office' in (a) can be understood as the focus of the question, that is, whether this is the time when 'you' talked to 'her,' but the preposed clause in (b) is not necessarily an 'integral semantic component' of the main clause (Diessel, 2013: 348).

8. a. Did you talk to her while she was still in her office?
   b. While she was still in her office, did you talk to her? (Diessel, 2013: 348)

In terms of intonation, post-posed adverbial clauses are found relatively more separated from the main clause, i.e., an intonation break may be found in between the two clauses (also see Section The Interpretation of Adverbial Clauses for exceptions); on the contrary, preposed adverbial clauses are usually intonationally bound to the main clause (cf Ford, 1993).

Semantic Types of Adverbial Clause

Traditionally, adverbial clauses are classified according to the semantic relations of the events depicted in different parts of a complex sentence or different chunks of discourse. The exact number and labeling of these semantic relations vary. All languages are reported to use the adverbial clauses (or a subset of the relations) listed in (9) (cf Kortmann, 1997; Givón, 1990; Thompson et al., 2007); other relations found in all European languages include Instrument/Means 'by,' Degree/Extent 'insofar as,' Exception/Restriction 'except/only that,' (Negative) Concomitance 'with(out)' (Kortmann, 1997).

9. Time (Simultaneity Overlap/Duration/Co-Extensiveness 'when/while/as long as,' Anteriority 'after,' Immediate Anteriority 'as soon as,' Terminus 'since,' Posteriority 'before,' Terminus 'until,' Contingency 'whenever');

Place 'where';
Manner 'as, how';
Cause/Reason 'because';
Purpose (Purpose 'in order that,' Negative Purpose 'lest');
Result 'so that';
Condition (Condition 'if,' Negative Condition 'unless,' Concessive Condition 'even if');
Concession 'although';
Contrast 'whereas';
Addition 'in addition to';
Substitution 'instead of, rather than';
Similarity 'as, like'

One would assume that not all of these semantic relations are equally central to human cognition. Indeed, there is evidence suggesting roughly a dozen cognitively most central relations, including simultaneity (overlap 'when,' duration 'while'), place ('where'), similarity ('as'), cause, condition, and concession (Kortmann, 1997). For example, the latter three relations are found in all the European languages that mainly use finite adverbial clauses and these three also have the largest number of adverbial subordinators in the European languages. Moreover, the adverbial subordinators marking the core relations tend to be more reduced morphologically, much more frequently used, and older than those marking the peripheral relations (Kortmann, 1997).

Simultaneity and cause also figure prominently in a large-scale semantic analysis of nonfinite adverbial clauses. In addition, nonfinite adverbial clauses are frequently interpreted in the sense of addition/concomitance ('and at the same time'), as in (10) and exemplification/specification ('e.g., i.e., in that, more exactly'), as in (11).

10. a. There he sat, wearing a white golfing cap.
    b. Sam threw himself to the ground, dragging Frodo with him.
11. a. Shares in Midland were worst hit, falling at one time 42p.
    b. He paid the closest attention to everything Lenny said, nodding, congratulating, making all the right expressions for him.

Therefore, not all semantic relations are equally important in different structural types of adverbial clauses. Likewise, their relative importance as coherence relations depends on the type of discourse. For instance, cause, condition, and concession play a much more important role in academic writing than they do in narrative fiction, where temporal relations as well as, for nonfinite adverbial clauses, addition/concomitance and exemplification/Specification account for a much higher number of adverbial clauses (see Kortmann (1991) for statistics and a discussion of relevant literature).

Functions of Adverbial Clauses in Discourse

Typically adverbial clauses provide background information for what is depicted in the main clause. But they serve additional functions beyond sentence level, contributing cohesion by linking sentences, paragraphs, or even the whole discourse. In interactive communication, adverbial clauses can also modify the speech act of the speaker, rather than the main clause.

The Functions of Adverbial Clauses beyond Sentence

Adverbial clauses help create coherent discourse (Chafe, 1984; Thompson, 1985; Givón, 1990; Ford, 1993; Couper-Kuhlen and Kortmann, 2000; Thompson et al., 2007; Diessel, 2013). Depending on whether they precede or follow their main clause, adverbial clauses produce more global (or textual) coherence or more local coherence, respectively. Preposed adverbial clauses serve a kind of guidepost or scene-setting function for the reader or listener by (1) linking back to what has gone in the (not necessarily immediately) preceding sentence, paragraph, or discourse and (2) preparing the background for what is going to follow in the complex sentence and often even a whole chunk of discourse. By contrast, post-posed adverbial clauses typically have a much more local function, i.e., their scope is restricted to their immediately preceding main clause. They neither reach back into earlier parts of the discourse, nor fore-shadow or prepare for what is going to follow. For example in written English, the preposed purpose clauses usually contain issues from preceding discourse, whereas the post-posed ones often describe purposes of the main clauses (Thompson, 1985). Accordingly, the subject of a post-posed adverbial clause typically is identical with the main clause subject, whereas the subject of a preposed adverbial clause is often identical with that of (one of) the preceding sentence(s).

Speech Act Adverbial Clauses

In addition to the adverbial clauses that link main clauses, sentences, or paragraphs as introduced above, some adverbial clauses function at the level of interactive communication by modifying the speech act of the speaker and are called 'speech act' adverbial clauses (cf Rutherford, 1970; Kac, 1972; Sweetser, 1990; Thompson et al., 2007; Diessel, 2013). Two examples are given in (12). Instead of setting a condition for the event in the main clause, the 'if' clause in (12a) expresses the speaker's attitude that he or she may not be in a position for making the statement in the main clause; similarly, the 'because' clause in (12b) does not state the reason for Harry to be late, but the reason why the speaker states that Harry will be late, i.e., the speaker talked to Harry's wife, through which he or she knows that Harry will be late (Diessel, 2013; Thompson et al., 2007).

12. a. And if I may say so Mr Speaker … they possibly derived some benefit from the presence of the Chancellor …. [International Corpus of English] (Diessel, 2013: 345)
    b. Harry will be late, because I just talked to his wife (Thompson et al., 2007: 267).

The Interpretation of Adverbial Clauses

Problems of interpreting adverbial clauses not only arise for the inherently vague nonfinite adverbial clauses, but also for some finite adverbial clauses. World knowledge or contextually grounded knowledge is important for the interpretation, but

formal (i.e., morphological, syntactic, and prosodic) features may also crucially influence the process of interpretation. For example, polysemy is observed for almost one-third of the adverbial subordinators in the European languages, especially for those with a high text frequency (Kortmann, 1997). This section introduces some of the most important relevant features that may influence the interpretation, always provided that the given language allows for a choice (e.g., has no constraints such as the obligatory use of the subjunctive mood in subordinate clauses or subordinate clauses generally preceding their main clause) (for further discussion see Kortmann (1991) and König (1995)):

i. Choice of tense and/or mood in the adverbial clause and, accordingly, in the main clause. For example, many languages use different tense (and mood) for the three semantic types of conditional: present tense (indicative mood) in factual/real conditional clauses (13a), past tense (or subjunctive mood in some languages) in hypothetical conditional clauses (13b), and past perfect (or a conditional perfect) in counterfactual clauses (13c).

13. a. If she comes home, I will be very happy.
    b. If she came home, I would be very happy.
    c. If she had come home, I would have been very happy.

Tense constraints also hold for the two different meanings (temporal and causal) of English 'since.' 'Since' can have a temporal reading in two situations; being used with past tense is one of them (see the other in (16)). Mood is also adopted in many (e.g., Romance) languages to help differentiate result ('so that') and purpose ('in order to that') that share the same adverbial subordinators: indicative mood leads to a result reading, subjunctive mood to a purpose reading.

ii. Nonsubordinate word order. As introduced in Section The Structure and Distribution of Adverbial Clauses, German usually uses verb-second word order for independent clauses and verb-final word order for dependent clauses. However, the verb-second word order is also typical in spoken German for post-posed *weil*-causals and *obwohl*-concessives clauses. An example is given in (14).

14. Ich hab das mal in meinem ersten Buch aufgeschrieben. Weil dann glauben's die Leute ja. ('I've written that down in my first book. Because people believe it then.')

iii. Intonation. One relevant intonational feature is the presence or absence of an intonation break: only when the complex sentence in (15) is read as a single intonation group does the adverbial clause receive a concessive conditional reading ('even if').

15. "I wouldn't marry you if you were the last man on earth" (Kortmann, 1997: 92 from Haiman, 1986).

iv. The choice of verb forms. The dependent versus independent verb forms were shown to be relevant in (i) already (indicative vs. subjunctive mood). (16) illustrates the impact of the choice between finite and nonfinite form in the adverbial clause on the interpretation of an adverbial subordinator, here 'since': when introducing a free adjunct, 'since' can only receive a temporal reading; a causal one is impossible (cf 'since' in (i)).

16. Since working with the new company, Frank hasn't called on us even once.

v. Constituent order, more exactly the relative order of adverbial and main clauses (cf Kortmann, 1991; König, 1995; Diessel, 2001, 2005, 2008). In English, for example, the great majority of present-participial free adjuncts receive a temporally sequential interpretation relative to the main clause (Kortmann, 1991). That is, the order of events is presented iconically by the relative order of adverbial and main clauses, as illustrated by the minimal pair in (17).

17. a. She uncurled her legs, reaching for her shoes.
    b. Reaching for her shoes, she uncurled her legs.

Abstract

Advertising agencies are the most significant organizations in the development of advertising and marketing worldwide. An advertising agency is an independent service company, composed of business, marketing and creative people, who develop, prepare, and place advertising in advertising media for their clients, the advertisers, who are in search of customers for their goods and services. Agencies thus mediate between three different but interlocking social groups: industry, media, and consumers. The history of advertising is largely the history of the advertising agencies that have served the needs of these three groups. They link industry and media by creating new forms for messages about products and services; industry and consumers by developing comprehensive communications campaigns and providing information thereon; and media and consumers by conducting audience research to enable market segmentation. This article is concerned with the origins, early developments, organization, compensation arrangements, and accounts of contemporary full-service advertising agencies.

An advertising agency is an independent service company, composed of business, marketing, and creative people, who develop, prepare, and place advertising in advertising media for their clients, the advertisers, who are in search of customers for their goods and services. Agencies thus mediate between three different but interlocking social groups: industry, media, and consumers. The history of advertising is largely the history of the advertising agencies that have served the needs of these three groups (*see* Advertising: General). They link industry and media by creating new forms for messages about products and services; industry and consumers by developing comprehensive communications campaigns and providing information thereon; and media and consumers by conducting audience research to enable market segmentation.

Origins and Early Developments

Advertising agencies are the most significant organizations in the development of advertising and marketing worldwide. They came into existence in the United States in the mid-nineteenth century and, later, elsewhere because of the mutual ignorance of the needs of newspaper publishers and would-be advertisers and because of the opportunity for profit provided by both parties' desire for economic assistance. Initially, advertising agents facilitated the purchase and sale of space. In so doing they promoted the general use of advertising, helped advertisers find cheaper and more effective ways of marketing goods, and served to inform the public of the existence of those goods. They acted as a crucial bridge between the activities of selling products and of mass communication at a time when both were undeveloped and expanding rapidly (*see* Journalism; Mass Media, Political Economy of).

The first advertising agents were colonial postmasters in America who accepted advertisements for inclusion in newspapers. In 1843, Volney B. Palmer set up the first independent agency, soliciting orders for advertising, forwarding the copy, and collecting payment on behalf of newspapers that had difficulty in getting out-of-town advertising. This *newspaper agency* was the first of four stages through which the business of the advertising agent proceeded to pass. In the second *space-jobbing* stage, the agent became an independent middleman who sold space to advertisers and then bought space from newspapers to fill his orders, driving a hard bargain with both. In 1865, George P. Rowell initiated the third *space-wholesaling* phase when, anticipating the needs of advertisers, he bought wholesale from publishers large blocks of space that he then resold in smaller lots at retail rates. Finally, in 1867, some agents contracted annually with the publications they represented to buy in advance the entire advertising space of particular newspapers, thereby acquiring the *advertising concession* in a publication. Similar processes of development can be found outside the United States, in countries such as England, France, and Japan, where advertising agencies also owe their early existence to the buying and selling of newspaper space.

Although the early agency business was often a confusing amalgam of these different arrangements, one element was common to them all and has continued to some extent to the present day. Advertising agents found themselves in an equivocal position as they attempted to serve two masters: on the one hand, the *publishers*, on whose behalf they sold advertising space and, on the other, the *advertisers*, to whom they acted as expert and 'impartial' advisors in the placement of their ads. In other words, right from the start, the advertising agency business has invited conflict between the diverse interests of the advertiser, the agent, and the media in which advertising is placed.

It was in order to overcome such a potential conflict of interests caused by space brokering that the idea of an 'open contract plus commission' was introduced. For the first time, in 1875, N. W. Ayer & Son entered into a formal arrangement that enabled a client to use the agency's services exclusively in exchange for payment of a fixed compensation based on the amount of advertising it billed each year. This so-called 'billing' system soon spread and is still widely used by advertising agencies. It is the gross billings posted by advertisers, rather than the actual payments received by agencies from their

clients, which are today used to gauge the relative size of the world's advertising agencies and their industries.

There were two important social consequences of the introduction of a contract between agency and advertiser. First, under the space brokerage system, advertising agents were in constant danger of being squeezed between advertisers and publishers. The open contract, however, permitted the agent to represent the advertiser *as well as* the publisher. Not only this, but it established the agency's relationship to a *client* rather than to a customer which hitherto had given its business to various different agents.

Second, by entering into a contract with an advertiser, an agency's profits were tied to the amount that its clients billed. Its growth was thus linked to the economic well-being of the advertisers it represented, so that even today an agency's prosperity is totally determined by the prosperity of its clients. When the economy is buoyant, advertisers spend and agencies flourish; when there is a recession, advertising appropriations are cut back, and agencies struggle. Such close ties can extend to agencies' organizational expansion. When advertisers' business interests lead them to set up international offices abroad, their agencies often follow. This explains the establishment, growth, and commanding presence of American agencies in most advertising industries worldwide, although English agencies tend to have a strong presence in former British colonies. In Japan, too, a buoyant domestic market has led to the growth of major Japanese advertisers served by Japanese agencies that have resisted American dominance and followed their clients abroad, especially into East and Southeast Asia (*see* International Advertising).

Full Service Agencies

What is known as a full-service agency is an agency that handles the planning, creation, production, and placement of advertising for its clients. It may also handle sales promotion and other related services as needed by individual advertisers. In short, a full-service agency offers its clients a complete range of services beyond the preparation and placement of their advertising.

The development of the full-service agency goes back to the last quarter of the nineteenth century, when mounting competition forced agents to think of other services that they might offer (potential) customers besides the placement of their advertising. One of these was marketing. In 1879, N. W. Ayer & Son conducted its first market survey in a successful attempt to wrest a large advertising account from a competitor. This led to the implementation of advertising planning, as agencies gradually took over the functions of studying the actual and possible markets for the commodities sold by their customers and of devising plans to fit into the general strategy for tapping those markets.

It was at this time, too, that agencies first became involved in what is now known as 'creative' work. N. W. Ayer & Son, and Catkins and Holden were among the first agencies to help advertising become a profession rather than a mere business transaction when they began to write advertisements for their clients, instead of simply placing their finished ads in newspapers. As a result, as well as sending salesmen out to sell space to customers, some advertising agencies began to create, plan, write, and design the copy and artwork that went into every ad. They then produced the necessary plates, and placed them with the publishers.

There were two significant reasons underlying agencies', at first reluctant, move into the creative side of advertising. First, they recognized that the ineffectiveness of a poorly written advertisement (contracted or written by the advertiser) was sure to redound against their fledgling business. Second, they found themselves operating in a highly competitive environment in which increased skill was demanded in the writing of advertising in order to make it stand out effectively. Moreover, new forms of advertising (magazine and outdoor) were being introduced. This necessity for distinction in the preparation of copy was made more urgent by technical advances in the printing and engraving trades. These made possible a more plentiful use of color and illustration, but they also complicated the work of advertising agencies.

Later technological innovations created further opportunities for agencies to develop into new areas of expertise and so come to be seen as essential partners in the advertising endeavor. Radio, for example, offered an entirely new medium of entertainment (and advertising) dependent on sound alone (*see* Radio as a Medium). Within three years of its first transmission, and in spite of the immense technical difficulties involved, agencies had begun to take an active part, not only in the preparation of advertising commercials, but in the planning and production of radio programs. These included continuity drama or 'soaps' which, almost from the very first, were supported by advertising and publicity.

The advent of television, which became popular in most industrialized countries from the 1950s, also obliged agencies to sail further into uncharted territory – this time by learning how to combine sound and images in cinematic form (*see* Television: General). As television advertising became ever more popular, dominating print advertising in many parts of the world, and as agencies continued to be active in the planning and production of media outputs, they found themselves coming into more frequent contact with production companies, celebrities, model agencies, film studios, stylists, photographers, animators, and others in the entertainment world. The latter decades of the twentieth century, therefore, have seen the formation of increasingly close ties among the advertising, media, and entertainment industries (*see* Celebrity; Entertainment).

Besides 'above-the-line' advertising in the four main media of television, newspapers, magazines, and radio, full-service agencies have found themselves moving into 'below-the-line' activities involving all sorts of areas of contemporary life hitherto untouched by advertising. Some – like the ads found on the backs of Australian postage stamps during the reign of Queen Victoria and of British dog licenses in the 1920s and 1930s – have ceased to exist. Most others, however, remain. At this point it seems unlikely that the advertising currently found on airport baggage trolleys, grand prix racing cars, telephone cards, professional sports equipment, and the backs of tickets of all kinds will, short of legislation, fall into disuse.

To further improve the services that they already offer their clients, advertising agencies have in many respects acted as 'cultural intermediaries' between the economy and culture of contemporary societies. This means that they have begun to

move away from the four main media that sustained the advertising industry throughout the whole of the twentieth century, and to invest in new business opportunities, including merchandizing, telemarketing, and e-commerce. The commercial sponsorship of sports, art, and other cultural events that became prominent in the 1980s and 1990s has also been driven by advertising agencies which now look for further opportunities to show their skills in matching their clients' needs for publicity and advertising to the everyday lives of consumers (*see* Mass Media and Sports). This development of 'promotional culture' has led to agencies participating in everything from the development of animation programs in consultation with television networks, supported by product placement and character merchandizing on the part of toy and other manufacturers, on the one hand, to the arrangement of marriages between celebrities, on the other. In many respects, agencies can best be described as the black boxes of cultural continuity and change.

Agency Organization

Many agencies in Europe and the United States have been founded by two entrepreneurs: one a creative person, the other a salesman or account manager. For example, the J. Walter Thompson (JWT) agency was founded by husband-and-wife team of Stanley Resor and Helen Resor who focused on management and copywriting, respectively. While, at first, they may have handled all aspects of their advertising business themselves, eventually they were obliged to take on employees with different areas of expertise and add divisions to handle the basic areas of responsibility in a full-service agency. Although agencies differ in the way they are organized, the main functional areas of a full-service agency are: (1) *account management*, (2) account planning or *research*, (3) *media planning* and buying, (4) *creative* services, and (5) *internal* services (dealing primarily with finance, personnel, and traffic). They are usually led by a chief executive officer (CEO) and one or two vice presidents, who may oversee a board of directors whose members represent different areas of their agency's responsibility.

The exact weight given to the work of each functional area has varied over time and differs also both by agency and by country. During the first half of the twentieth century, emphasis was placed by such famous copywriters as Claude Hopkins on a scientific approach to advertising – an approach supported by the founding of research organizations by A. C. Nielsen, George Gallup, and others. Later, in the 1960s, led by such creative advertising people as 'Marlboro man' Leo Burnett, David Ogilvy, and William Bernbach, art, inspiration, and intuition became the industry's buzzwords. The 1970–90s saw a return to hard-sell advertising in what was called the era of 'accountability.'

How do these different areas of responsibility work in practice? When an agency wins a new account, it generally forms a cross-department account group, or account team, composed of an account supervisor (who is often supported by account executives), account planners and media buyers, as well as a creative team made up of copywriter and art director with, as necessary, a producer (for television and/or radio commercials). The account group proceeds along more or less predetermined lines. First, the account planning department works out and solves a marketing problem by conducting new, and making use of previous, research to find out who the targeted consumers (known as 'prime prospects') are; what their demographic characteristics might be; how the product to be advertised fits into their lifestyle; what they think of this and competing products; what the most suitable advertising medium for the product in question might be; and so on. On the basis of answers to these questions, account planners (who are sometimes simply referred to as 'marketers') formulate a strategy that positions the product in relation to targeted consumers and emphasizes the attribute(s) that will appeal to them.

Once the overall marketing strategy has been determined, the agency's creative team works on an appropriate creative strategy, writes copy, and prepares rough layouts and storyboards. At the same time, the media buyers need to work out a media plan that accords with the marketing strategy, to select an appropriate mix of media, and prepare schedules with costs. These three separate plans are then amalgamated into a single package by the account supervisor and presented to the client, which may or may not get involved in different stages of the agency's preparations along the way. The extent to which an advertiser 'interferes' in its agency's work depends very much on the company concerned. However, evidence suggests that, for reasons that will be explained below, agencies tend to work much more closely with their clients in Japan than they do elsewhere in the world.

One of the main organizational difficulties facing any account group is that it invariably finds itself having to deal with two different audiences whose interests may not be the same. On the one hand, account planners and the creative team focus their attention on how to advertise and sell a product to a particular targeted group of *consumers*. On the other, the account supervisor and his supporting account executives need to liaise between the *advertiser* and the agency, being responsible for interpreting the client's marketing needs to their colleagues, on the one hand, and selling the marketing, creative, and media plans to the client, on the other. Since it is the advertiser who pays the agency for its services, it may disagree with – and occasionally overrule – the consumer-oriented strategy proposed by its agency's account group.

A second organizational difficulty that often emerges in the work of an account group is internal and concerns the different attitudes towards advertising held by account planners, on the one hand, and creative people, on the other. The very *raison d'être* of account planning is to form marketing strategies based on objective, scientific criteria derived from in-depth qualitative and quantitative data. These data then have to be transformed into creative images by copywriters and art directors who usually claim to work according to intuitive, artistic ideas that may have little actual relationship to the expressed marketing aims. Sometimes conflict between the two types of advertising agency employee results and adversely affects the work of the account group which, ideally, needs to blend harmoniously to achieve its client's aims.

Agency Compensation

It was noted earlier that advertising agencies started out as brokers of space on behalf of newspaper publishers who paid

them a commission for their services. Traditionally, this commission has amounted to 15% of the media cost. It may be more for some kinds of advertising (for example, outdoor), or less for certain advertisers whose account an agency, for one reason or another, prizes highly enough to accept a lower commission. In addition to media commissions, agencies may charge a production commission for production work subcontracted (type, photography, and illustration). Here the client is charged the cost of the work involved, plus a 17.65% commission.

As seen above in the actual creation of an advertising campaign, agencies have often found themselves dealing with the conflicting interests of two different partners. The very existence of the commission system has, historically, encouraged the advertiser to try to pay less than the sum demanded by the medium in which it sought to place its advertising. As a result, advertising agencies often found themselves caught between a desire for profit, on the one hand, and a need to retain its business, on the other. This has led, and in some parts of the world still leads, to agencies playing off one partner against the other, as they seek rebates from the media in which they place their clients' advertising, but pass on the full cost to the advertisers concerned.

It is to offset this problem of business ethics that fees have been introduced. This form of compensation is comparable to that used to pay lawyers or accountants. Agency and client agree an hourly fee for the agency's work, to which are added charges for out-of-pocket expenses, travel, and other standard items. No commission is paid on media costs which are billed net of commission. As a rule, advertiser–agency compensation arrangements are negotiated according to the specific requirements of the advertiser and the willingness and ability of the agency to fulfil those needs at a mutually agreeable cost. Over time, the fee system has come to predominate over the commission system in the United States, although in many other countries the commission system, or a combination of fee and commission, is still the norm. It seems likely that in future the fee system will prevail, in which case the traditionally close reciprocal ties between advertising agencies and media organizations will probably weaken to some extent.

The Account System

The sum of money put aside by an advertiser and allocated to an agency for the purpose of selling a particular brand or product group, sometimes through a selected medium, is called an account. It is an advertising agency's job to persuade an advertiser that it is best suited to take on a particular account. To this end it will embark on active solicitation with the aim of being asked to participate in a competitive presentation or 'pitch' in which, together with other agencies, it will present marketing and creative strategies based on the advertiser's initial orientation of its needs. The successful agency will be asked to take on an account, usually for a fixed period, and will then enter into partnership with its new client.

The relationship between agency and client is ideally a professional one, involving a considerable exchange of confidential information which may include, for example, plans for new products or marketing strategies. As a result, when awarding an account, an advertiser will not usually permit its agency to handle companies or products with which it is in direct competition. This is known in Europe and the United States as the *competing account rule*.

The rule about an agency's not handling competing accounts means that, whenever it wins a new account that conflicts with one already being handled, it has to decide which of the two accounts it wishes to keep. Competing accounts are also often a deciding factor when, as has happened frequently since the 1980s, agencies decide to merge, although many such large agencies run their local offices independently. This they do in the hope that their clients will not regard the same type of account being handled in another office as being in competition and thus not raise an objection.

So far as the organization of the advertising industry is concerned, the competing account rule ensures two things: first, that there is a continuous circulation of accounts among agencies; and second, that no agency ever becomes excessively large. As a result, by comparison with other industries, the organizations that make up the advertising industry are quite small.

Although the competing account rule is the norm in almost all countries of the world, an alternative system of distributing advertising appropriations exists in Japan where advertisers split their accounts by product, media, or a combination of product and media, and do not object to the same agency handling a number of competing accounts. Thus large advertisers like Toyota or Kao, for example, contract more than half a dozen different agencies to handle the advertising of their numerous products. These same agencies may also be handling the accounts of rival car or toiletries manufacturers.

The *split account system* has advantages for both agencies and advertisers. Precisely because the overall advertising appropriation is divided, accounts in Japan are not nearly as large as they are elsewhere. This is to an agency's financial advantage when it loses an account, since the sheer number of accounts in circulation means that it can usually make up the financial shortfall and is not obliged, as it might be in the United States or Europe, to lay off staff. In this respect, the split account system contributes to the overall stability of the advertising agency, and of the industry of which it is a part.

Advertisers are able to use the split account system to play off one agency against another since they alone have full knowledge of their overall marketing strategy. This not only enables advertisers to minimize the problem of confidentiality that so worries those working in advertising industries elsewhere. They can use their knowledge strategically to operate a system of divide-and-rule that obliges agencies to keep in constant touch with client personnel, as well as with other agencies and media organizations, in order to gain as much information as possible about their clients' overall plans and activities. In other words, the split account system encourages much closer interaction among the three main players in the advertising industry.

There are disadvantages to the system. One result of the need for Japanese agency account executives to keep in constant touch with their clients is that advertising decisions tend to be based on personal likes and dislikes, rather than on more

objective professional criteria. Another, claimed by agencies, is that they are prevented from producing effective advertising because their clients do not give them access to their *total* marketing strategy. All in all, however, the advantages appear to outweigh the disadvantages within the Japanese advertising industry. In this respect, it is significant that in the autumn of 1999, Procter & Gamble, one of the world's biggest spending advertisers, decided to divide its worldwide advertising appropriation into nine different brands and to distribute these accounts among nine different advertising agencies. It is possible, therefore, that in future the system of split accounts will become more popular with advertisers outside Japan, thereby altering the relationship hitherto developed between an agency and its clients.

Editor's Note

Since Moeran's entry was first published, the key developments in the world of advertising agencies have been globalization of the industry and the emergence and spectacular growth of internet advertising. On the former, an essential reference is Faulconbridge et al., 2011. On the latter, see David and Evans, 2014. Also useful: Sheehan, 2013.

Abstract

This article offers a definition of advertising, followed by brief descriptions of its function from various points of view (traditional economics, Marxist cultural theory, and so on). The forms advertising has taken over time and in various cultures are described and analyzed with an eye to the implications for consumer response. In particular, the claim that advertising is primarily an 'image' genre, is disputed. Then, a few elements that might constitute an 'aesthetics of advertising' are proposed. Lastly, various theories about 'how advertising works' are described and discussed.

Definition

The way the terms 'advertising' and 'advertisement' are defined depends to a great extent on the author's perspective, training, and agenda. Even so, an encyclopedia entry seems to beg for an authoritative definition. This article offers the following: an advertisement is a message paid for, but not delivered, by the sender, that (1) incorporates technologies or forms other than speech, (2) appears in a public forum, and (3) attempts to persuade receivers to behave in a way that brings direct economic benefit to the sender. This definition allows for most of what is customarily considered advertising, while excluding other acts or forms that, while sharing some characteristics with advertisements, are not generally considered such. For instance, this definition would not include a salesman's pitch, but would encompass any brochures he used. Political speeches, whether made in Parliament or during the breaks on *60 Minutes*, would not be 'advertisements' because the expected behavioral outcome is not directly economic. Corporate 'image' messages would count, even when purchase is not the object, as such advertisements ultimately have an economic goal, such as affecting the value of stock by increasing the prestige of the corporation.

Function

The function of advertising likewise will vary in description based upon the education, focus, and motive of a particular author. Economists traditionally have allowed 'advertising' into their models only as a form of market information. Their definition of 'information,' however, is usually limited to prices and availability. To the extent that advertisements incorporate other 'non-information' (such as prestige claims or sex appeals), advertising becomes an 'exogenous variable,' constitutive of 'tastes,' and therefore present in the system only as noise or interference. As long as advertisements serve to notify markets of supply and price, however, the institution of advertising operates neatly within the range of traditional economic models. Indeed, to the extent that advertising supports stable demand, allowing producers to become price-makers rather than price-takers, it becomes an important aid to microeconomic planning. The realization of economies of scale that accrue from such an arrangement, so the argument goes, tends to reduce prices to consumers in the long run.

Critics and consumer groups often charge that advertising merely adds to the prices paid by consumers – sometimes raising them as much as 100% – but such claims do not hold for most goods in the long run. For example, simple bar soap was sold 100 years ago in the US at a price that included advertising expenses equal to direct costs (thus representing about 50% of each unit's price). As consumption of soap grew, however, the advertising expenditures leveled off (advertisement budgets reach a plateau of effectiveness beyond which it makes no sense to spend at higher levels). Consequently, the percentage of each unit's price represented by advertising steeply declined. Since advertising expense is only one of the economies of scale created by mass marketing and production, the total unit price of each bar of soap also dropped dramatically, allowing many US citizens to wash regularly for the first time. Today, it is only the very extraordinary soap that would include an advertising expense more than 3% of its unit price. The same is true for most well-established, mass-produced, and heavily advertised products.

In the Marxist critique of capitalist consumer culture, advertising's most central function is to ensure capitalism continues: by stimulating ever-increasing levels of demand, advertising forces an always-growing array of goods into consumers'homes, regardless of need or utility. Here too, advertisements that inform audiences of availability and prices are not typically thought problematic. However, the 'fetishization' of objects by advertisements that name, sing, or tell stories is seen as a sinister form of industrial 'magic' through which consumers are made to value products for the wrong reasons. By adding this dubious 'exchange value' to the object's 'use value,' advertising serves to rob workers and pad the pockets of capitalists with unearned profits.

The cultural critics' picture of advertising as a guarantee of long-term profits is sharply at odds with the way advertising's function is actually viewed in practice. Though the most obvious reason for a manufacturer to spend money on advertising is to stimulate purchase, advertisers are famously skeptical about the actual impact of media budgets on sales. They tend to feel vaguely robbed by their advertising agencies, forced to participate in a pointless display by social convention. And, indeed, one of the few generally accepted findings of the past 30 years of academic research on advertising effectiveness is that a direct effect on sales is virtually impossible to demonstrate. So many factors influence sales

that it is hard to isolate advertising's function to stimulate demand. And, from case to case, advertising's apparent performance can vary from spectacular to abysmal with little readily discernible logic.

Accounting practices reflect the doubts of the manufacturing community: advertising cannot be treated as an investment in capital (like buying a new plant), but must be treated instead as an annual expense (like office paper). Only in the past 5 to 10 years (and only in Europe) has the possibility of recognizing the long-term benefits of advertising in financial statements been discussed. The reason for reconsidering advertising as an investment is the equity markets' valuation of companies with established brands. Consider that shares in Procter and Gamble, the largest advertiser in the US, go for more than four times book value. The price of the stock reflects the financial community's belief that some value inheres in Procter and Gamble beyond the historical cost of its equipment, patents, and real estate. Probably, the financial markets are imputing a value for Procter and Gamble's many brands, most of which are long-standing leaders in their respective product categories. Category leadership is at least partly attributable to Procter and Gamble's historical practice of consistently advertising each brand at levels that exceed all direct competitors' expenditures.

Historians have offered the view that advertising's function is to weaken, even eliminate, the 'middlemen' in goods distribution by stimulating consumer demand for products. Once consumers want a particular brand, they say, retailers are 'forced' to carry it on their shelves and brokers are 'forced' to provide it to retailers. While it is demonstrably true that the growth of advertising as an institution over, say, the past 150 years has resulted in a 'rationalizing' of distribution systems in a way that is advantageous for manufacturers (and, actually, consumers), the notion that advertising allows makers to control distributors should not be overstated. Distributors and retailers retain a great deal of power in the current system and, in fact, during the last 30 years of the twentieth century, the shift has been back toward the distributor. We see evidence of this in the production of private label brands, the growing power of stores like Wal-Mart, and the broadscale shift of advertising dollars spent by companies like Procter and Gamble into expenditures for trade allowances and the like. Further, while it is certainly plausible that advertising has had the effect of increased control over distribution, arguing that channel management is actually the primary function of advertising conflates 'effect' with 'function.'

The conflation of the terms 'effect' and 'function' is also a problem in works that purport to identify the impact of advertising upon social issues. For example, many feminists have written about the effects of advertising on the status of women, frequently falling into the habit of claiming that advertising's function is to oppress women. While advertisements may indeed contribute to the ideology of gender inequality, arguing that advertising's purpose is the oppression of women seems a misplacement of emphasis.

From the broadest cultural perspective, advertising's function may be more meta-structural than most social critics would describe – or advertisers pay for. Anthropologists argue that the primary function of consumption is cultural, not biological, because goods serve to make the categories of culture visible and, therefore, stable. Since human cognition demands a balance between total heterogeneity and total homogeneity, any system of objects will require an activity that marks items as being appropriate for certain users, places, or occasions. In pre-industrial societies, marking is accomplished through exchange rituals performed in the presence of the entire tribe. The chanting, singing, and naming in such rituals can be uncannily similar in form to modern advertising. Given the proliferation of otherwise homogeneous goods in the mass-production society, one would expect to see some mechanism arise for marking these goods as cultural artifacts. Since mass production was accompanied in history by the emergence of mass communication, it is, perhaps, not terribly surprising that the activity of marking mass-produced goods would occur in the public 'spaces' provided by the mass media. Thus emerges advertising 'as we know it.'

Form

Today, advertising is highly identified with images. Particularly in cultural studies, invoking the dangers of the visual is almost synonymous with advertising criticism. But advertising is not necessarily, nor even distinctively, visual in form. Television commercials that use only the visual dimension are as rare as silence on a sitcom – that is to say, rare indeed. Instead, television advertisements, like most other types of advertising, skillfully integrate more than one symbolic system (speech, writing, numbers, music, gesture, and so on). In radio, where the visual dimension is absent, the sound of speech is often elaborated with rhyme and rhythm or augmented with song or 'sound effects.' Furthermore, the largest category of advertisements, directory and classified advertisements, are usually composed entirely of written text. Even here, however, we see nonverbal dimensions brought to bear. The addition of color, use of stylized typefaces, and strategic placement of written messages in all forms of print emphasize something cultural critics try to ignore: that writing is itself an image; the printed word is, by definition, speech made visible.

Writing systems, furthermore, are not always alphabetic in nature, but are sometimes based on picturing. The first shop signs operated on a kind of pictography, even in alphabetic societies, because only the elites were literate. Thus, the convention of hanging the shape of a shoe outside a cobbler's door, or painting a striped pole to designate a barber, or differentiating taverns by the visual representation of their names (the 'Bull in Boots'). Critics who insist on situating advertising in the industrial period argue that such signs were not a form of advertising because they were merely 'information,' an 'announcement' rather than an attempt to persuade. The range of early signs includes many aggressive, even poetic, pictorial statements, however. In England, the signs became so huge and outlandish that they began to cause accidents by falling or blocking the view – in 1762, they were outlawed.

Today, imagistic advertisements still reach into common linguistic forms – proverbs, colloquialisms, jargon – for the sense of their message. In the advertisement in **Figure 1**, for instance, the association between 'duck' and 'duct tape' has no basis in use: one cannot buy ducks from amazon.com, nor can ducks be customers of amazon.com, nor, for that matter, would duct tape be used on a duck. The association here only 'works' because, in speech, the phrase 'duct tape' sounds like 'duck tape.'

Figure 1 Visual use of speech sound similarity.

Figure 2 Adaptation of familiar image.

The multiform nature of advertising is at least partly a result of the ongoing struggle to garner consumers' attention. In the early years of advertising's growth in the USA, most publishers limited advertisements to ten-point agate type. This policy, known as the 'agate-only rule,' was an attempt to equalize commercial competition and a way of saving paper. Inventive advertisers strained against the agate-only rule by printing their messages in patterns, sometimes getting notice through sheer repetition and other times by using the text to form a picture. When, eventually, publishers allowed advertisers to make use of images, the pressure only escalated. Now, advertisers wanted bigger pictures, more distinctive pictures and, especially, color pictures. The same struggle occurred in aural form during the early days of radio. The competition to stand out, be memorable, or gain credibility resulted in testimonials by leading radio stars, jokes woven into the existing program, jingles put in with the music. The Internet advanced in less than 5 years from a text-only medium to a jumbled screen offering pictures, words, numbers, sound, animation, and even video. While the proliferation of formal features on the Internet was certainly made possible by technological innovation, it was also largely fueled by the demands of the new commercial media, the 'dot.coms,' wanting to coax their reluctant customers, national advertisers.

Advertisements have also adopted the formal features of other genres. Early in the century, for instance, the advice columns of the new national magazines in the USA were quickly imitated by advertisers, who used their own 'experts' to give advice that inevitably involved buying a particular brand. Today, advertisements like the one in Figure 2 reach all the way to fifteenth-century Italian art for their inspiration, leading cultural critics to bemoan the 'pastiche' that seems to crop up so often in advertisements. However, advertisements like this one (and others that adapt genres like movies or comics) also testify to the growth of an elaborate visual vocabulary among the reading populace.

As this visual vocabulary builds, even the images of the past become meaningful to the readers of the present. Thus, we see frequent adaptations of older styles reused to specify a past period. For instance, the typeface, background and headline in Figure 3 all communicate 'the late 1960s.' Yet this advertisement ran on the back of *TV Guide* in the autumn of the year 2000: many of those readers would not be old enough to remember the 1950s or 1960s, but nevertheless are clearly expected (by the advertisers) to know the style associated with that time. Achieving specific reference through subtle variation in the manner of rendering is a hallmark of advanced pictographies. Advertisements like these demand a highly developed form of reading from their viewers, as opposed to the kind of mindless absorption that most critics attribute to consumers of the 'image culture' of advertising.

Though references to the visual past appear frequently in advertising today, it is also true that in our own era – as in others before us – most advertisements struggle to look 'modern' (and here I mean 'hip,' 'new,' 'cutting edge,' etc.) The same is true in other dimensions, such as music: the first Pepsi jingle was in the swing style popular on radio in the 1930s; in the 1960s, Pepsi used Motown artists; in the 1980s, Michael Jackson and Madonna sang for Pepsi. As a result of this propensity to operate right at the horizon of a culture's formal style, advertisements are consistently among the most topical,

Figure 3 Use of visual style to periodize.

timely, and stylish of cultural texts. Thus, the advertisements of any period tend to be, if nothing else, distinctly 'of their time,' heavily 'periodized.' As Roland Marchand noted, for instance, the advertisements of the 1930s are markedly different from those of the 1920s – more aggressive, less graceful, more pronounced in commercial intent. He attributed the difference to the declining economy. So, not only do the latest visual styles, celebrities, tunes, and dances feature heavily in advertisements, the issues and concerns of the day do as well. This influence may occur in pervasive ways, such as Marchand described, but it also makes itself felt in very specific, identifiable instances. War imagery and patriotic motifs, for instance, are much more common in US advertising between January 1942 and August 1945 than they are in the months either immediately before or immediately after. Fear of disease is the basis for many advertising appeals following the influenza epidemic of 1918; today's advertisements refer to AIDS and breast cancer. Ideology is also reflected: Thomas Frank's *Conquest of Cool* (1997) has eloquently argued that the change in advertising known as the 'Creative Revolution' had its roots in the broader political shift that rumbled through the USA between 1960 and 1970.

If one were to try to theorize an aesthetics of advertising, therefore, a key characteristic might be this tendency to focus on the present, even while evoking the past. Another, which has been noted by authors like Jennifer Wicke, is that advertising is essentially an aesthetics of economy: saying a lot in a small space or a short time is nearly always one of the objectives. Roland Barthes' famous observation that advertising is generally characterizable by its 'frankness' – in the sense that advertisements try to seem natural – is not, in my opinion, supportable. Instead, advertising's need to 'defamiliarize' its propositions has created a corpus of texts notable for whimsy, fancy, outrageousness, and blatant artifice. A good example is a television commercial running now, which refers to the 'animal nature' of a Jeep by having the car shake mud and water from itself like a wet dog, showering its owners in the messy residue. The fundamental impulse to animate an object in the context of exchange – something that is present even in so-called 'primitive' cultures – here runs directly into the expressive capacity of early twenty-first century technology. A simple metaphorical proposition ('a Jeep is like a dog') is transformed, via computer animation, into an extraordinary fiction. The expression of a very basic material proposition in highly imaginative form would also probably be one of the key principles of an aesthetics of advertising.

For all its fictive properties, however, advertising is unlike other art forms in one very mundane way. Advertisements always have 'one foot on the ground' in the sense that they attempt to influence a concrete behavior, usually a purchase. Depending on the particular government under which it is operating, an advertisement may also have to accommodate practical concerns about the product or the status of exchange in some formal way. Commercials for drugs that stimulate weight loss, for instance, often represent attractive possibilities – followed abruptly by disclosure of some rather unattractive side-effects. Many other products, from toys to cigarettes, must include warnings or disclaimers about everything from health risks to whether batteries are included. Regulations on deceptive advertising, at least in the USA, will tolerate a range of fiction and puffery, but the inferences the average consumer makes about the product must be concretely true or the campaign is pulled. What that means, then, is that most US viewers probably do not expect a Jeep to shake like a dog, even after seeing it on TV. In fact, looking at the total range of fancy discernible in advertisements today, viewers must be making, rapidly and on a daily basis, some fairly fine distinctions between the fiction of the advertisements and the facts about the products. This, again, suggests a more skeptical, sophisticated, selective viewer than many who write about the 'manipulation' of the populace by advertisers prefer to imagine.

Raising the specter of an 'aesthetics of advertising' among those who actually make advertisements often revives a long-standing philosophical debate over what 'a good advertisement' is. On one side are those who believe that 'a good advertisement' is one that sells, even if it irritates every member of the audience. Famous admen like Rosser Reeves took this position in the 1950s. Others like Bill Bernbach, who led the Creative Revolution of the 1960s, have argued that 'a good advertisement' is one that is more 'creative' (that is, prettier, funnier, more imaginative, or in some other way a more pleasing work of art), but have also claimed that aesthetically pleasing advertisements actually sell more product anyway. Such positions are hard either to evaluate or defend because of the previously-mentioned difficulty of demonstrating the effect of advertising on sales. These positions are made even more

problematic by the changes over time in (a) what is deemed to be a pleasing advertisement and (b) what is deemed to be a persuasive argument. For instance, in the 1950s, anything that smacked of science gave an aura of 'rationality' to the argument. Today, those same advertisements, with their secret ingredients, graphic cross-sections, and microscopic views, look as irrational as the sci-fi movies of the same period. Several campaigns of the Creative Revolution, like Alka-Seltzer and Volkswagen, still appear on industry 'best campaigns' lists 40 years after they were created. But others, like the Braniff campaign, are a puzzle to contemporary viewers – the Pucci costumes and 'Pop' planes aren't as fresh to today's eye.

Aesthetic notions are always closely connected to a culture's morality. Thus, outside the practical world of advertising, the distinction made between 'good' advertising and 'bad' advertising is often seated in the presumed value of 'information' versus the moral questionability of 'persuasion.' Writers trying to support such divisions among advertisements often use the presence of images as the basis for categorizing: words and numbers tend to be seen as 'informative' or 'rational,' while images are 'persuasive' and 'irrational.' Even an amateur rhetorician, however, can come up with examples in which the display of alphanumeric information (or the withholding of it) is itself an attempt at persuasion. Further, the visual presentation of information – even in the plainest style – affects its persuasiveness. Finally, information is often presented in pictorial form, as in maps and graphs. In many cultures, visual forms are used to record and transmit widely varied types of data. Today, writers like Edward Tufte have made us more aware of the intimate connection between visualization and information, whether our objective is persuasion, 'mere representation,' or facilitating our own understanding. Therefore, the distinction between the informative–written advertisement and the persuasive–imagistic advertisement seems to rest mainly on a naïve understanding of rhetoric and an outdated approach to the pictorial.

How Advertisements Work

There are almost as many theories about 'how advertisements work' as there are advertisements themselves. Several famous admen have published their own treatises on how to make an effective advertisement. There is little agreement among them. Few, however, would subscribe to the theories that have been popular among academics. For instance, Freudian theories popular among cultural critics of the late twentieth century would inspire little more than laughter among those who actually produce advertisements. After a brief flirtation with Freudian notions in the late 1950s (an approach known in the business as 'MR,' which stands for 'motivation research'), the advertising industry abandoned attempts to sell products through subliminal cues, such as phallic symbols or 'hidden' images of genitalia. Such approaches, having proven ineffective, are now thought to be ridiculous. Shirley Polykoff (who wrote the 'Does she … or doesn't she' Clairol advertisements of the 1960s) ridiculed these attempts in her memoirs, published in 1975 (Polykoff, 1975). She recalls that a TV spot introducing a women's shaving cream was changed to accommodate a psychoanalyst's suggestion: after the woman shaved, her legs should rise slowly as she leaned back in her chair, 'a position normally associated with an activity other than shaving.' The product was a bomb: 'It turned out no woman at that time, rising legs notwithstanding, was interested in paying for a shaving cream when she could use her husband's or a bar of soap that was readily at hand'(Polykoff, 1975: p. 98). Cases like this one eventually put the MR people out of business.

Purchase behavior, as it turns out, is better explained by such pedestrian matters as price, practices, and preferences than by phallic imagery. So, in some ways, the subliminal advertising and motivation research fads of the fifties were displaced by a greater understanding of the reasons people consume. In *The Hidden Persuaders*, Vance Packard (1957) accused advertisers of manipulating 'hidden needs' to sell products, sparking a national controversy. Packard's 'eight hidden needs' were then thought to be irrational or even immoral as a basis for buying. Today, these needs – for self-esteem, for safety, for recognition – are no longer particularly 'hidden,' but are popularly accepted as being essential to human mental health. Further, scholars investigating consumption from a more anthropological point of view, like Mary Douglas and Mihalyi Csikszentmihalyi, have now published material emphasizing the complexity of consumption in all cultures, by all humans, and at all times. This literature richly and repeatedly illustrates the myriad of ways that people use material possessions to express themselves, to make connections with others, to protect their families, to enculturate their children, and so on. The tendency in Western post-industrial thought to insist on material life being properly separated from the spiritual or social does not hold up well under the weight of this evidence. A more sophisticated perspective now recognizes that people usually consume for social reasons even when they are satisfying biological needs: we eat dinner with our families because we need both nurture and nutrition. Indeed, the more inquiry is done on the dynamics of consumer behavior, the less currency is held even by the traditional split between needs that are biological (and therefore 'real') versus those that are social (and therefore 'false'). With this in mind, it becomes increasingly difficult to insist that advertising either plays on hidden needs or that it 'makes us buy things we don't need' – because the notion of 'need' becomes utterly redefined.

Elsewhere in academia, however, a different kind of psychology still tries to explain how advertisements work. Experimental psychologists in applied areas like advertising and marketing have tried hard to identify specific formal cues and appeals that will consistently produce sales for advertisers. These researchers design experiments that attempt to determine whether color, happy music, or big type 'work' better to sell us goods than black and white, sad music, or small type. After nearly 30 years of study, not a single generalizable finding has emerged from this research. The new psychological theories of 'how advertisements work,' therefore, are no more likely to win the respect of advertising professionals than the old, Freudian ones.

So, professionals approach the creation of advertisements in much the same way they always have: as a common-sense attempt to persuade their cultural kindred to buy a product.

True, they have a great deal of information about our needs, desires, and dissatisfactions – and they do put that knowledge to use in crafting their messages. To that extent, advertisers may have some edge over the amateur persuaders we meet in everyday life: Girl Scouts who try to sell us cookies, preachers who try to get us to tithe, and offspring who try to make us buy toys. Nevertheless, advertising professionals basically work with rhetorical principles as old as Aristotle: after studying their audience, they offer information and arguments they believe will be convincing. They affect a character they think will match up with the audience's self-image. For 'sweetening' the proposition, they throw in melodies, jokes, and pictures. At the workbench level, this practice, for all the devilry attributed to it, is only a garden variety of rhetoric.

Like any other attempt at rhetoric, some of these practical efforts fail. Some sink dramatically, like Shirley Polykoff's advertisement for shaving cream. Few produce the kind of powerful propellant critics claim for this institution. The public and its pundits, though, continue to believe that advertisers have some secret power to manipulate them. Some of this suspicion is the advertising industry's own fault. In promoting their abilities to press and potential clients, advertising agencies have consistently overclaimed for their own skills. Their bravado, coupled with continued attempts to find magic formulas, makes the public justifiably wary.

Many myths thus continue about the power of advertising, lending fuel to the general discomfort with commercial culture. For instance, the 1950s story of 'subliminal advertising,' in which unsuspecting US movie patrons were persuaded to buy cola and popcorn by flickering messages undetected in the film, is retold today as if it really happened. In actual fact, the whole event was a scam. James Vicary, the man who claimed to have accomplished this feat, was an unemployed market researcher when he reported his story to the press in 1957. While reporters and, soon, Congressmen investigated the validity of his claim, Vicary collected retainers from some of the nation's largest advertisers. But his claim quickly began to fall apart. First, the theater owner said no test had been done on his premises, as Vicary had claimed. Then, Vicary failed to produce the effect for a Congressional committee. Suddenly, less than 6 months after his name first appeared in the papers, Vicary disappeared. His closets and his checking account were left empty. He was never heard from again. Though many researchers have attempted to replicate his study, the purported effect has never been repeated. Even if Vicary was a charlatan, though, the true story does show that advertisers in the USA were willing to pay huge sums to learn how to advertise subliminally. So, however false this cultural myth may be, the suspicion of corporations that lies behind its continued viability is not without foundation.

Conclusion

Advertising seems to touch every aspect of life in the post-industrial world. As both form and institution, advertising is blamed for an array of social ills ranging from the mundane to the millennial. The poor standing advertising has in the global community at the opening of the twenty-first century is not based on the real existence of any secret formula, economic equation, or covert conspiracy. It is certainly not based on any demonstrable effect on prices, social conditions, or even sales. Rather, our attitudes toward advertising are probably a response to the rapid changes in everyday life brought about by industrial commerce, and are intensified by the knowledge that, at least some of the time, advertisers will make extreme attempts to have their way with the public. Nevertheless, the human mind, being far more subtle and sturdy than many theories would suggest, has shown remarkable resistance to all such attempts – the explosion of consumer culture notwithstanding. Our discomfort with advertising is also profoundly situated in ethnocentric prejudices against commerce, material comfort, sensual pleasure, and images. Rigorous thinking on the subject of advertising is rare – at least partly because we are blinded by these very fears and prejudices. Looking forward in a globalizing marketplace, however, should impress upon us the need to break out of such constraints.

Editor's Note

Scott's intriguing entry argues that the effectiveness of advertising is based largely on the power of persuasive rhetoric. A recent extension of this line of argumentation is Tom and Eves, 2014. Much recent literature in the advertising field deals with the effects of advertisements on children, especially food, alcohol and (at one time) tobacco advertisements. See Adams et al., 2012; Kelly et al., 2010; Smith et al., 2014; Hanewinkel et al., 2011.

Abstract

Like most other human activities, advertising needs to be 'controlled' – that is, its failures must be constrained and its potential to inform people must be optimized. There are two major alternative ways of achieving such control: (1) have the government issue laws and regulations and (2) have the industry develop an enforceable code of conduct. Both approaches have advantages and disadvantages, and the tendency is to blend the two approaches through 'co-regulation.' The co-regulatory systems of advertising control in France and the United Kingdom are analyzed together with technological and social trends.

Advertising is a form of paid communication between a firm and its (potential) customers that uses independent media to communicate positive messages about a good or service. Firms supply it to generate sales and to counter their competitors' advertisements but there is also a demand for advertising because consumers lack information, and ads help lower inevitable 'search costs' – that is, consumers' expenditure of time and money to select what goods to buy.

Advertising Failures

Like other institutions, advertising is prone to natural shortcomings (e.g., information is always incomplete and often asymmetric) and artificial imperfections (e.g., agreements and rules *not* to advertise among professionals such as lawyers). The huge number of laws, regulations, and self-regulatory guidelines reveal that many advertising practices represent actual or potential failures that negatively impact the market system's dependence on adequate information and effective competition, and that impair the functioning of other societal institutions. Consequently, the control of advertising focuses on the use of monopolistic power, consumer misleadingness and deception, unfairness and social irresponsibility.

Monopolistic Power

Producers can erect 'barriers of entry' to better and cheaper products by creating and using meaningless distinctions among brands in their advertisements. Furthermore, they may collude to ban advertising as has often been in the case of legal services but such rarely challenged restraints negatively impact competition and consumer welfare. Even associations that join advertisers, advertising agencies, and the media have been opposed in the United States because they could collude to eliminate certain advertisements.

Consumer Misleadingness and Deception

An advertisement cannot be as lengthy as an instruction manual or even a label but should it include all significant information? This depends on how one defines 'information.' Do people want and need only objective facts such as origin, ingredients, price, performance, and contraindications? Or should information refer to any data or arguments that put forth the attractiveness of a good in the context of a consumer's own buying criteria such as socio-economic background, personality, lifestyle, aspirations, experience, and other factors – whether rational, emotional, or simply habitual? Thus, should government-sponsored lottery ads reveal that the odds of winning are abysmally low, such lotteries pay back the smallest share of any legal game, and the government's take is not fully or mainly used to support education or the arts, as was promised? Or should one accept the appeal of 'All you need is a dollar and a dream' because it reflects the needs of lower-income people? Still, all perspectives on information assume truthful communications although some puffery is tolerated (e.g., The King of Beers), and rules often require that advertisers should be able to substantiate their claims (e.g., The fastest copier).

Unfairness

'Unfair' means 'not sincere, frank, honest, loyal, and right' – all subjective criteria. Unfairness is associated with particular practices such as denigrating through 'comparative advertising' a competing product or firm even if the latter is in fact inferior. Playing on the fears of people may also be considered unfair even when such fears are real (about sickness, death, looks, social status, self-confidence, etc.) and could be alleviated through the advertised products and services (e.g., insurance and cosmetics). Although its legal definition varies across countries, unfairness usually involves: (1) malice (e.g., nobody mentions a competing firm to say good things about it); (2) benefits (e.g., relief) being significantly outweighed by costs (e.g., monetary loss and personal distress), and/or (3) the exploitation of the weaker by the stronger (e.g., large retailers out-advertising smaller ones).

Social Irresponsibility

Advertising should not undermine other institutions such as the state, the family, and the value system. Thus, advertising to children is thought to weaken parental authority and to develop consumeristic attitudes at an age when more important values should be impressed on the young. Larger and

evolving questions about societal welfare and personal happiness are also involved. Thus, as a 'mirror of society,' does advertising reflect and magnify developments in ideologies and lifestyles through new symbols and habits that are detrimental to these goals? Is it even part of a plot to create a 'culture of consumption' essential for the capitalistic machine?

Extent of Advertising Failures

There are no counts of misleading, unfair, or irresponsible advertisements even though as many as 50 million *new* ads may be issued each year in the USA alone, if one includes all national and local media but excludes Internet ads and personal ones – the latter a frequent source of deception (e.g., 'attractive man wants to meet intelligent woman'). The self-regulatory UK Advertising Standards Authority (ASA) once estimated that some 2% of British ads appeared to violate some provision of its extensive Code of Advertising Practice. This is a low rate of malfeasance, compared to other institutions (e.g., the family and the educational system) and considering that much advertising misbehavior results from ignorance and carelessness rather than ill intent. Still, 2% of many millions of advertisements add up to hundreds of thousands of failures worldwide, suggesting a significant need for control mechanisms readily usable by competitors, consumers, governments, and concerned citizens.

Forms of Advertising Control

Theory

Theoretically, the control of advertising is justified by the 'negative externalities' created by false, misleading, unfair, and asocial ads. Its desired outcome is the creation of 'public goods' in the form, for example, of the punishment of infractors, whose benefits are distributed among the populace at large. However, the main problem facing all private-interest groups such as self-regulatory bodies is that of the 'free rider' who benefits from the reputation and services of an association but does not join or participate in it – either by not paying dues or by violating its guidelines. This problem is avoided by the fact that, in the case of advertising, all violations are traceable because all advertisements are visible and nameable by definition so that free riders can always be detected and prosecuted – compared to many other trade violations, which may be hidden as in the cases of collusion (cartels) and the delivery of inferior goods.

The spread of co-regulation (see below) may be associated with the shift from 'imposed' to 'contracted' institutions emerging from below (i.e., the practitioners) instead of the top (i.e., the government) and which are capable of creating social obligations to which powerful actors may be bound outside and beyond their own rational egoism. These contracted rules commit firms to internalize costs – that is, the moral as well as financial costs which it would be beneficial for them to shift unto consumers, the public, and the environment – an evolution currently related to the development of 'corporate social responsibility.' Still, by occasionally constraining the domain of rational-economic action, co-regulation may help forgo opportunities for dynamic marketing innovations as well.

Mechanisms

Most practitioners and organizations behave themselves because they want the esteem of other members of society, they fear losing customers, they feel threatened by the law, and/or they want to lessen uncertainty about their rivals' behavior. The community reacts to advertising's shortcomings by ignoring, discounting, and/or opposing it (e.g., defacing posters and criticizing tobacco ads). Individual and organizational self-discipline, in the forms of personal ethics and company codes of conduct (including media acceptance codes), provides another vehicle for community-based control. Market responses include consumers shunning the goods of unreliable advertisers, and competitors countering ads with their own. State sanctions involve prohibition, restriction, obligation, taxation, and government ads, and they aim to facilitate legal action by customers and competitors. Under industry self-regulation, peers rather than outsiders establish and enforce voluntarily self-imposed rules of behavior although such private governance may be mandated, regulated, and monitored (see below). Since most ads require the use of media (the press, broadcasters, postal services, telephone companies, Internet service providers, etc.), the latter's participation in self-regulation helps put an effective stop to objectionable advertisements.

Respective Strengths and Weaknesses of Alternative Systems

Effective control ultimately requires: (1) developing standards; (2) making them widely known and accepted by practitioners and the public; (3) advising advertisers and agencies before ads are released; (4) pre- and post-monitoring of compliance with the standards through checks and surveys; (5) handling complaints from consumers, competitors, and other affected parties; (6) penalizing bad behavior in violation of the standards, including the publicizing of wrongdoing and wrongdoers, and (7) obtaining legitimacy for the system from the government and the public at large. Somebody has to design, perform, and fund these sizable tasks.

In this regard, community control offers freely shared norms (e.g., against vulgarity) and broadly based pressure (e.g., boycotts) but lacks authoritative means to mobilize social resources beyond what can be obtained voluntarily on account of regard for others. Market competition generates more and better information but is weak on broader social-responsibility issues. Government regulation benefits from universal coverage, compulsion, and legal enforceability although it may also impose high costs, stifle innovation, and be limitedly effective in dealing with complex and evolving issues such as decency and the reach of foreign media. Industry self-regulation can provide customer and competitor protection beyond the minimum standards of the law, and it benefits from the positive commitment of practitioners although industry support of a self-regulatory system is insufficient and unstable in underdeveloped countries.

While the law may engender feelings of personal irresponsibility, effective private rules rest on values and the freedom of those over whom they apply. These rules rely on the autonomy of economic actors that are free and responsible within a moral system which they have created for themselves. However, this

Table 1 Strengths and weaknesses of advertising regulation and self-regulation

Advertising – control tasks	*Government regulation*	*Industry self-regulation*
Developing standards	+ Greater sensitivity to politicized concerns – Difficulty in elaborating standards for taste, opinion, and public decency – Inertia in amending standards	– Greater lag in responding to such concerns – More informed ability to develop and amend standards in these areas + Faster response in amending standards
Making standards widely known and accepted	+ Everybody is supposed to know the law – Compulsory nature of the law generates industry hostility and evasion	– Difficulty in making the public aware of the industry's standards and complaint mechanisms + Greater ability to make industry members respect both the letter and spirit of voluntarily accepted codes and guidelines
Advising advertisers about gray areas before they advertise	– Usually not provided by government	+ Increasingly promoted and provided by industry for free or for a fee, and even mandated in the case of broadcast media and some products (toys, cosmetics, nonprescription drugs, etc.)
Monitoring compliance	± Routinely done or at the prompting of others but often with limited resources	± increasingly done by the industry although restricted by financial resources
Handling complaints	+ Impartial treatment is anticipated + Potential to handle many complaints – Slow and expensive when using the courts – Cannot put the burden of proof on advertisers in criminal cases	– Treatment more likely to be perceived as partial – Limited capacity to handle many complaints in some countries + Faster and less expensive + Usually puts the burden of proof on the challenged advertiser
Penalizing bad behavior, including the publicity of wrongdoings and wrongdoers	+ Can force compliance – Generates hostility, foot-dragging, appeals, etc. – Limited publicity of judgments unless picked up by the media, competitors, and activist groups	– Problems with noncompliers but the media usually refuse to carry ruled-out ads + More likely to obtain adherence to decisions + Extensive publicity of wrongdoings and, to a lesser extent, of wrongdoers
Obtaining legitimacy for the system from the public at large	+ The state is expected to act in the public interest	– Private interests are suspected of favoring industry at the expense of customers + Increasingly perceived as a necessity for self-regulatory control

(+) refers to strengths, and (–) to weaknesses.

system must be open to its external stakeholders' demands for participation, impartiality, objectivity, transparency, and accountability – as backed up by the state, if necessary. However, government participation in rule-making and sanctioning changes the system into one of 'co-regulation' whose equilibrium may be precarious because it challenges its members' voluntary internalization of certain values, participation, and support. Table 1 summarizes the respective strengths and weaknesses of the regulatory and self-regulatory systems which dominate advertising control.

Factors Affecting the Use of Controls

The demand for controls reflects, first, the fact that competitors want to protect their property rights in brands and reputations (e.g., against comparative ads) and to ensure fair competitive rules (e.g., against bigger advertising subsidies granted to large distributors) and; second, that customers and their associations are concerned about consumer deception, advertising unfairness, and social irresponsibility. On the supply side, governments are increasingly tackling such issues through regulation and the support of stronger market competition and self-regulation. Industry has offered self-regulation as a way of preempting or mitigating public regulation and of improving the overall credibility of advertising. The proliferation of national and subnational states as well as of supranational bodies (e.g., the European Union and the World Health Organization) has multiplied mandatory rules and advisory guidelines which have facilitated complaints, the stopping of ads through cease-and-desist injunctions, private suits and even class actions by empowered competitors, consumers, and citizens.

Regulation and self-regulation are often complementary. Thus, all voluntary codes state that "Advertising must be legal" although very few self-regulatory bodies (e.g., the UK Advertising Standards Authority) pursue statutory infractions. Sometimes they specialize, as with the German ZAW body focusing exclusively on taste and decency because the law against unfair competition applies to most other problems. Governments burdened by growing tasks and budget deficits increasingly invoke the principles of 'proportionality' and 'subsidiarity' whereby higher control levels should not deal with what better informed and motivated lower levels can achieve more effectively. Even consumerist groups may agree to this approach, provided they can meaningfully participate in self-regulation.

These developments reflect better knowledge about how advertising works and about the effectiveness of controls. Thus, research has confirmed that: (1) market shares keep shifting when comparative advertising is allowed, with the latter practice helping reduce consumer search costs; (2) government restrictions often result in higher prices and lower quality of

services, and (3) the cost of preventing and correcting all harm to consumers, competitors, and citizens can be excessive. In this regard, the US Supreme Court now requires that, when public policy justifies government controls, the latter be shown to be effective and not disproportionate to the goal to be achieved.

Both regulation and self-regulation are being fostered and assisted by supranational governments (e.g., the European Union's directives on misleading and comparative advertising), international organizations (e.g., the World Health Organization's generation of a global treaty to control tobacco sales and advertising), and industry groups (e.g., the International Chamber of Commerce with its International Code of Advertising Practice, and the European Advertising Standards Alliance (EASA) and its promotion of self-regulation within the European Union).

Still, the existence of some 200 nation-states with varying traditions, values, legal systems (common law vs civil or religious laws), economic resources, and advertising experiences precludes the standardization of controls. Besides, industry conventions and public regulations are culture-specific and not readily transferable to very different political and socioeconomic environments. In particular, if distrust largely prevails among people, self-enforcing voluntary mechanisms are unlikely to work.

Impacts

Self-regulatory bodies handle up to 30 000 complaints a year (with some duplications about the same ad) when they are actively solicited as by the UK Advertising Standards Authority, and the US Federal Trade Commission received 1.8 million of them in 2011 although this number includes many fraudulent and anticompetitive misbehaviors rather than advertising ones. However, the number of adjudicated cases can be relatively low (about 200 a year by the very active US National Advertising Division of the Council of Better Business Bureaus) when these bodies choose to focus on exemplary cases designed to send strong signals or break new grounds. Government agencies are also very selective in their interventions for the same reasons and because of budgetary constraints although courts are increasingly handling advertising cases in developed countries.

Contract law potentially protects customers everywhere against misrepresentation in advertisements. Private suing to stop advertisements or for damages has become common although usually done more by competitors than by consumers. The latter are slowly being empowered to bring class actions against companies whose products cause injury (e.g., cigarette advertisers). Under statutory law, certain practices are forbidden, circumscribed, or mandated (e.g., health warnings) and criminally punishable but public regulatory bodies can also issue civil-law-based cease-and-desist injunctions as well as require corrective advertisements. Self-regulatory codes are being expanded to include more products (e.g., toys and food) and services (e.g., advertising by charities) as well as new media (e.g., Internet advertising) and novel claims (e.g., about environmental effects).

How effective have regulation and self-regulation been in promoting truth, accuracy, fairness, social responsibility and competition? No precise evidence exists, and impacts vary depending on a country's level of development as well as on its priorities. There will always be crooks so that control mechanisms can only aim at improving the overall quality of advertising at a reasonable cost through exhortation, coercion, punishment, denial of access to the media, and other mechanisms. Besides, new problems keep emerging on account of technological innovations (e.g., the Internet and satellite broadcasting that ignore national borders and regulations), new entrepreneurial initiatives (e.g., sports sponsorship and political advertising), and citizen activism (e.g., growing concerns about the environment, children advertising, obesity and privacy invasion).

One can reasonably conclude that such problematic practices as unsubstantiated claims about weight reduction and other cures have been significantly curbed in developed countries through regulation and self-regulation. Besides, the principle that advertisers have a 'prior reasonable basis' before making a claim has been broadly adopted and enforced in many states. More ads about particular goods and in certain media (particularly, broadcasting) must be approved in advance and certain claims (e.g., 'free, low-fat, and environmentally sound') are now restricted while mandated information (e.g., annualized interest rates in financial ads) is growing.

However, controls have also curbed competition and denied valuable information to consumers, as with bans on pharmaceutical, liquor, medical products, and legal services advertising in many countries. Besides, protecting a lengthening list of 'vulnerable groups' (the young, the sick, the recently bereaved, the poorly educated, etc.) shrinks the pool of those targetable by advertising.

Ongoing Developments

Technology

Means of reaching consumers keep multiplying in such forms as satellite broadcasting, international editions of newspapers, magazines and catalogs, and the Internet. However, technology also allows consumers to avoid ads (e.g., with zapping devices) and to access them only voluntarily and selectively, and it facilitates the fast sharing of information among consumers, associations, and governments as well as the filing of complaints. The Internet increasingly links advertisers, customers, and citizens via computers, television sets, and telephones as well as other receivers and processors. Potentially, there will be many more millions of Internet ads that can be quickly reformatted as well as many more advertisers, including individuals. The line between editorial content and advertising message, which have traditionally been separated, will become blurred because there will be many 'banner' ads as well as sponsors linked to entertainment and information programs. Advertising agencies that help screen ads will be less involved to the extent that some of their services are now available from Internet-service providers for free or at a low cost. Surprisingly, the Internet has generated a complementary advertising controller – namely, bloggers who comment on current ads and even recirculate banned ones! Blogging allows people at large to share opinions and to applaud, deride, or criticize advertisers' campaigns.

Another major current issue concerns 'online behavioral advertising' (OBA) which refers to the collection of data from

a particular computer or device regarding Web viewing behaviors for the purpose of using such data to predict user preferences or interests and to deliver advertising to that computer or device, based on what has been inferred from such Web viewing behaviors. Governments and industry are working on what transparent information should be given to consumers about how OBA works and what action they can take to block it if they so choose.

Current Issues

Every day sees the launch of non-governmental-organization (NGO) campaigns and government legislative proposals directed at restricting marketing and advertising practices. Much of it is driven nowadays by concerns about obesity and the perception that advertising plays a negative role in encouraging unhealthy diets and lifestyles. This issue is on the global policy agenda of the World Health Organization, the US government, the European Union, and many other industrialized countries. The pressure is building to find simple regulatory solutions to what are, in fact, complex and wider societal problems. Media visibility of the obesity issue is high as is the pressure on individual food companies. For some firms, it threatens their license to trade.

Yet, it is important to realize that advertising and its control have low 'salience' in the minds of consumers. For example, a 2008 survey conducted by the UK's Advertising Association, which groups all major members of the advertising industry, found out that people are much more concerned about the current cost of living (81% of respondents), crime, law and order (76%), and health and welfare issues (68%) than about greater government regulation of advertising (15%) which is viewed by 64% as a good way to find out about new products. Besides, 73% of people know that advertising is controlled by rules and regulations while 79% realized that there were UK organizations overseeing the industry – that is, that self-regulation existed. Actually, 47% of the respondents had themselves used advertising to find something they were looking for in the last 6 months!

Laws and Codes

Regarding the right to give and receive information, national constitutions usually guarantee freedom of the press because democracies need independent media to challenge governments in 'the marketplace of ideas.' However, does this right cover what is called 'freedom of commercial speech?' Since the 1970s, the US Supreme Court has come to acknowledge such a right also supported by the Council of Europe's Declaration on Freedom of Expression and Information, and by Article 10 of the European Convention on Human Rights. However, this new freedom is limited because it conflicts with growing 'rights' to health, privacy, and sex equality – for example, pharmaceutical advertising remains restricted because it may lead to greater health expenditures by governments on account of greater demand for drugs, which can be incited by ads.

Regulation and self-regulation will proliferate at industry, subnational, national, and supranational levels, thereby making their harmonization more difficult. Such heterogeneity will complicate the creation and delivery of ads although large advertisers can more readily comply with varying rules. It also creates loopholes to advertise from where restrictions are lower, and to sue where litigation is most likely to succeed. Besides, more controls encourage the use of imagery ('Things Go Better with Coke') in lieu of challengeable claims ('Canon prints faster than HP'). When ads emanate from another sovereignty, both regulation and self-regulation face the problem of 'conflict of laws' in terms of what body, domestic or foreign, decides the case, what procedures (e.g., about required evidence) to follow, what law or code is applicable, and how to recognize and enforce decisions. Governments now favor the laws of the ad's country of origin, and so does the self-regulatory EASA as well as international codes for pharmaceuticals and direct marketing.

Regarding the Internet, regulatory control will focus on: (1) criminalizing the sending of certain advertising contents (e.g., pornography and pharmaceuticals); (2) having advertisers and service providers notify ad receivers of private data-collection practices (particularly from children) and of their rights to check these data's accuracy and to be assured that such information is secure, and (3) obligating access providers (including telecommunication companies) to at least respond to complaints since it is impossible for the latter to screen out millions of messages. Hence, the Internet will test and refine the control of advertising in coming years.

The Development of Co-Regulation in France and the United Kingdom

There is a trend in major developed countries toward some form of 'mandated self-regulation' whereby both rule-making and -enforcement are largely left to industry bodies. This system differs from pure voluntary self-regulation insofar as the private regulatory system is officially sanctioned by some government agency which monitors the program and, if necessary, takes steps to ensure its effectiveness. Thereby, nonofficial norms become part of the legislative order by insertion into statutes or by publicly acknowledging in various ways that the product of private negotiations is generally binding on the whole sector of advertising. France and the United Kingdom have made recent moves toward advertising co-regulation although their structures and processes differ significantly.

French Co-Regulation

French legislators have been reluctant to deal with freedom-of-expression issues while their laws bearing on communication and the media have often been ill-conceived and worded so that the French executive government has been happy to delegate rule-making to the self-regulatory system.

However, to be seen as credible and efficient as a 'moralizer of markets,' professional self-regulation must guarantee the effectiveness of its rules through a monitoring system and periodic assessment of its activities. This requirement is particularly important in France where advertising and its practitioners are widely distrusted on account of what are believed to be misleading ads and a shocking lack of values as well as assaults on vulnerable groups (e.g., children). In this context, the private enacting of rules and having them respected by 'professionalized' practitioners must be accepted by the

public – that is, legitimized. This issue manifested itself first in the matter of taste and decency.

The French ARPP (Autorité de Régulation Professionnelle de la Publicité/Professional Advertising Regulation Authority) had faced endless criticisms from consumer and feminist organizations whose ire was particularly directed at ads and commercials where sex was used inappropriately (e.g., being sexist or discriminatory), excessively, or in ways exceeding moral tolerance levels. In response, it developed the criteria of 'the dignity of human beings' and of 'non-discrimination,' it wrote Recommendations on them and it committed itself to report annually to the appropriate ministry about its pursuit of ads violating its guidelines.

Going further, its leadership created in 2008 three new committees including independent members from outside the advertising industry: (1) an advisory Advertising Ethics Council chaired by an independent academic to 'anticipate' new societal developments; (2) an Advertising Parity Council, of which half the members represent consumer and environmental associations and which 'concerts' with industry representatives about the need for new self-regulatory rules, and (3) an independent Advertising Deontology Jury made up exclusively of people with no links to industry or consumer associations in order to solicit and 'sanction' complaints from the public as a complement to the ARPP's monitoring of advertisements. However, new 'Recommendations' have to be approved by a board made up exclusively of industry representatives because, otherwise, they are no longer voluntary and cannot be truly internalized by the ARPP's members.

The Advertising Deontology Jury, which solicits and handles complaints from the public, reported for 2010, 47 valid complaints, 23 of which were related to the protection of human dignity and, in 14 of these cases, the complaint was upheld. Still, public complaining and negative jury decisions are likely to persist because viral advertising on the Internet and word-of-mouth diffusion have created a huge recirculation of advertisements with sexual and violent content.

ARPP sanctions include the publicizing of wrongdoings and wrongdoers ('name and shame') and wide press publicity of its decisions. Members cannot be excluded since adhesion is voluntary but very few culprits challenge the Jury's decisions. Fortunately, most French media belong to the ARPP and, therefore, are committed to stop the diffusion of the proscribed ad after a negative decision of the Deontology Jury which accepts complaints from everybody: consumers, competitors, and members of the public. Besides advising practitioners before ads are issued, the ARPP also monitors large random samples of ads and reports annually its findings to the appropriate ministry. For example, only 0.7% of monitored ads were found to violate its Recommendations in 2009 although the Internet incurred a much higher proportion of violations than other media.

The ARPP system of 'professional regulation' has been publicly recognized in several ways. Thus, a 5 March 2009 law, which transposed into French legislation the recent European Union directive on audiovisual services, officially authorized the government to delegate the preclearance of television commercials to the ARPP. Subsequently, a government agency in charge of controlling the media delegated the task of screening commercials before their diffusion to the ARPP but the French government has also left to it the control of ads in such sensitive areas as taste and decency (see above), ecological claims, and food advertising.

In addition, the Paris Appeals Court stated on 26 October 2010 that "recommendations from the ARPP, even though they have no legal character, are professional practices that the judge must take into account if they do not contradict a legal statutory measure."

Altogether, professional regulation is now acknowledged and accepted by the French government which, through several Commitment Charters, has implicitly agreed *not* to regulate or ban certain practices but requires in exchange an effective system of adequate guidelines as well as an accountability evidenced by periodic and transparent monitoring and reports. These agreements amount to a system of co-regulation between public and private actors who concert and collaborate in the public interest, and help generate a sense of responsibility among advertising professionals now convinced that their industry cannot claim its freedom of commercial speech if it cannot prove its responsibility.

British Co-Regulation

The ASA is the British advertising self-regulatory body whose aim is to insure that ads be 'legal, decent, honest, and truthful to the benefit of consumers, business, and society,' and it is the most active one in the world. Thus, the ASA solicited and received over 30 000 complaints about ads in 2011, including over 10 000 of them on company websites and such online spaces as social networks and video on demand, which these firms control. Some 87% of the complaints pertained to small and medium enterprises – a percentage suggesting that many advertising misbehaviors reflect a lack of knowledge of the standards rather than malevolence. Clearly, the task of making standards known, understood, and internalized is an essential but endless one!

The ASA sponsors twice-yearly independently-run consumer surveys as well as awareness campaigns and focus-group meetings with parents, guardians, and children in order to better understand their concerns which are mainly related to the commercialization and sexualization of childhood. It provides copy advice before advertisements are released – on some 140 000 occasions in 2011 when its website was accessed by 750 000 visitors. All of these services are based on the principle that prevention is better than cure.

The ASA Council is the jury that decides whether advertisements have breeched the ASA Codes. Led by a notable British peer, two-thirds of this Council's 14 members are independent of industry while the remaining members have a recent or current knowledge of advertising or the media. It includes one or two younger members more familiar with contemporary lifestyles but mainly representatives of families, charities, and consumer groups. Handling complaints generally takes from 35 to 85 days and the decisions of the ASA Council can be appealed to an Independent Reviewer who can order the Council to reconsider its decision (close to 50 of them in 2011). The ASA has set itself high standards of service and it reports regularly on such goals as accessibility to members of the public and of the advertising industry, speed in handling complaints, user satisfaction, high-quality professional service, transparency, and accountability.

A large and growing staff assists the various rule-making, advisory, screening, monitoring, sanctioning, and appeal functions of the ASA which is financed by an automatic levy of 0.1% of all advertising expenditures – a sound financing system only emulated in Ireland and the Netherlands, and which has allowed the ASA to cover the vast media of Internet advertising and company websites.

In 2004, after more than 40 years of successful independent self-regulation of nonbroadcast ads, the ASA assumed responsibility for TV and radio ads after the newly formed Office of Communications (Ofcom) took the decision, in a move supported by Parliament, to contract-out responsibility for broadcast (TV and radio) advertising to the ASA system in a co-regulatory partnership. This agreement created for the first time a single regulator for advertising – a one-stop shop for advertising complaints, which is particularly important for members of the public who want a complaints system that is easy to navigate.

While the advertising member associations of the ASA must approve the changes in their main codes – the UK Code of Non-Broadcast Advertising, Sales Promotion, and Direct Marketing and the UK Code of Broadcast Advertising, Ofcom has the right to single-handedly change these rules in the case of broadcast advertising when there is a specific statutory duty to work toward a public-policy goal that markets alone cannot achieve.

It is generally agreed that a state regulator operating with backstop power is necessary for a co-regulatory system to work properly. Besides, third-party advice must be solicited by the ASA from consumer experts, civil-society organizations, and the public at large – just as the French do. Even when control is not completely in the hands of the national government, the inclusion of external stakeholders broadly representative of civil society (consumers, families, women, etc.) as partners in major functions of the self-regulatory system is crucial in terms of avoiding capture of the regulatory state by industry.

In 2007, new Ofcom rules pertaining to the broadcasting of food commercials forbade their use before 9.00 p.m. on television channels devoted to children's programs or those programs likely to be of particular appeal to children below the age of 16 in the case of food or drink assessed as high in fat, salt, and sugar under the principle that ads should not condone or encourage poor nutritional habits or unhealthy lifestyles in children. Advertisers had to comply with these unilaterally imposed rules which resulted in significantly reducing advertising during children's airtime, using ads with mothers and family rather than child appeal, eliminating promotions based on licensed characters (e.g., Tony the Tiger for Kellogg's Frosted Flakes), excluding toy inserts in packages, stopping websites designed to appeal to children, and removing under-16s from company databases. Besides, multimedia campaigns became complicated when what can be done in print advertising cannot be done on television. It is also worth noting that 'children' in other countries usually comprise only those under the age of 11.

Through its member associations, the ASA can have firms expelled from membership, it may impose mandatory pre-vetting (that is pre-checking and approval of ads) on persistent offenders, and it can refer rule violators to the Office of Fair Trading which can seek an injunction from the Court to prevent an ad's further appearance. Independent compliance surveys regularly reveal that more than 97% of ads are in line with the ASA advertising codes.

The British ASA and French ARPP were two of the founders of the EASA located in Brussels, which is the single voice of the advertising industry in the European Union as far as advertising self-regulation is concerned. Among its wide range of operations, EASA acts as a focal point for cross-border complaints so that consumers need to complain only to the self-regulatory organization in their country, no matter where the marketing communication originated. The EASA is a source of information and research on self-regulation, it helps develop new self-regulatory bodies in Europe, and it liaises with the European Union's numerous legislative and executive units. It has generally been rated as very effective by the relevant EU departments in charge of consumer protection.

In conclusion, consumers enjoy advertising's entertainment value and often make use of the information it provides but it is prone to a number of significant failures which public regulation, private self-regulation, and co-regulation have effectively addressed in order to secure high standards for the protection of businesses, consumers, and the general public.

Abstract

This article provides a review of the advertising effects literature. It begins by putting forward three reasons why so little knowledge about the effects of advertising exists. They are: an anticommercial bias, the inherent difficulties presented by the object of study itself, and inadequate methods. Effects at the economic, sociocultural, and individual level are presented and discussed. These findings are set in a social–historical context.

Introduction

The phenomenal growth of advertising in the twentieth century helped usher in and sustain a defining consumer culture. That is advertising's surest effect. Consumers come into contact with literally hundreds of ads every day. This ubiquity has its effects. People use phrases and other utterances from ads in daily discourse (McKay et al., 2011; Friedman, 1991; Ritson and Elliott, 1999), revealing more than mere mimicry, but also the ad-inspired consumer ethos of contemporary consumer culture. Advertising is now part of the interstitial tissue of daily life on this planet. Yet, the effects of advertising are often anything but clear or easily detected (Spielmann and Richard, 2013).

In fact, the effects of advertising run the gamut from obvious to perplexing and contradictory. On the one hand, most people, most of the time, don't care much about ads. They don't pay attention to them. But every now and then, they do. And even when they don't, the effects may still accrue.

Context

Advertisements have been studied in one way or another for about 100 years, yet we simply don't know much about their effects. There are at least three good reasons for this lack of knowledge. First, scholars have viewed advertising as unworthy of attention. This is the same high culture (and anticommercial) bias which led libraries to cut ads out of magazines before binding them for decades. Many libraries gave space to pornography but not advertisements. It was politically difficult to propose studying something that was regarded as thoroughly unworthy of study. This bias has had a profound effect on this scant scholarly enterprise. Relatively little research has been done, and much of it is more polemic than systematic. Second, the object of study itself presents an inherent difficulty. Advertisements are by their nature textual, generally ephemeral, and encountered as a common social object, situated within layer upon layer of social discourse. They are here and then they are gone. They are commercial rhetoric, actively interpreted by various audiences in various ways. While the general meaning of an advertisement is informed and bounded by cultural forces so as to produce more likely than less likely interpretations, there is no single, objective advertisement to study (Fish, 1980; Scott, 1994). What an advertisement is depends on who is interpreting it and why. This seemingly simple point has thoroughly eluded most advertising researchers. Further, ads exist in their particular social–temporal microclimate and then they become something else (Lee and Joo, 2012). Even the once-legendary 'Man from Glad' is not now what he once was. Typically stripped of context, we have little idea of what advertisements meant in their own milieu.

The third reason for the paucity of work in this field is inadequate method. It is extremely difficult to demonstrate the effects of advertising, and the job is made even more difficult within the confines of a single method, a single literature, a single paradigm. Survey data suffer from the scores of variables that lie between exposure and behavior. Experiments suffer from low ecological validity; they too often have little or nothing to do with how real people experience and interpret real ads in real contexts. Ethnographic work on advertising has been rare, but suffers from its lack of generalizability, the effects of intrusion, and the privileging of informants and text. Textual analysis, and even reader response, suffers from the authority of the one constructing the interpretation. Work by economists with aggregate data suffers from a long and troubling list of assumptions, particularly those positing rational thought. Advertising is a sociotextual phenomenon, which does not travel well outside its natural environs. In their natural space advertisements are a typically trivial background to daily life. Methods sensitive to this reality have yet to be employed to any significant degree.

But advertising certainly must have effects. How could something so widespread, so much a part of contemporary existence, and something which businesses worldwide continue to invest in massively, have no effect? Beyond the reasonable and predictable retort that 'real' effects are not necessarily detectable and demonstrable effects, there must be something to which we can point and say: 'we (probably) know this.' The more robust advertising effects findings are reviewed below.

Economic Effects

Economists have studied the effects of advertising spending on various outcome variables such as GDP, aggregate and

category demand, brand switching, economic concentration, and barriers to entry. Borden (1947) was one of the first to attempt a systematic economic analysis. While acknowledging that advertising might increase 'selling costs,' (p. 881) his study points to the vital need for advertising in growing 'dynamic economies' (p. 881). He sees little downside to advertising. Running counter to this view are both Packard (1960), and Galbraith (1958), who see advertising as the engine of waste and the loss of consumer agency. These are not, however, empirical examinations, but more economic–philosophical theories. They represent the political left's view sans data.

Schmalensee (1972) conducted the next major empirical analysis of the economic effects of advertising. His work showed "that total national advertising does not affect total consumer spending for goods" (p. 85). He argues in a very real and practical sense that sales cause advertising, much more than the other way around. He goes on to say that a major implication of this is that "advertising cannot be all-powerful if it cannot influence the decision to save." He finds national advertising to be particularly inconsequential in driving aggregate demand. In terms of competition, he says: "the effects of national advertising spending by the various consumer goods industries cancel each other out in the aggregate" (p. 86).

The next major exhaustive empirical examination of advertising's economic effects is that of Albion and Farris (1981). Their work revealed a much more complex and nuanced set of findings than previously reported, but were generally supportive of Borden (1947) and Schmalensee (1972). In other words, most of the criticisms of advertising were not borne out by the data. They do, however, find advertising expenditures and industry concentration to be correlated, but argue that other factors, as well as reverse causality, may be at work (Kim and McAlister, 2011). Most significantly, they note the overwhelming importance of context in these effects. Schudson (1984) also makes the case for context and the limited power of national consumer goods advertising. He argues that advertising follows affluence, targeting consumers who already consume large quantities of the goods or services concerned. He gives good examples of both advertising without sales, and sales without advertising (Kim and McAlister, 2011). Luik and Waterson provide one of the more recent (1996) reviews of this literature and find that advertising affects aggregate demand early in a product's life, but as time goes by, has more of an impact on brand share, and less of an impact on aggregate demand. That is, for most mature product categories, advertising seems to impact on brand share, but not total category demand.

Sociocultural Effects

The cultural effects of advertising have largely been the purview of those in the humanities, as well as those in areas of communications, sociology, and anthropology. More recently, a few in marketing have contributed as well. A wide range of orientations and methods has been brought to bear on the search for advertising's effect upon societies and culture. This in fact constitutes the single largest (and most widely accessible) literature on advertising effects.

These works claim that advertising has produced several effects at the sociocultural level. For one, advertising is said to have caused a more materialistic culture (Ewen, 1988; Fox and Jackson Lears, 1983; Pollay, 1986; Richins, 1991). This argument rests on the traditional modernist critique: the real has been replaced with artifice, community with mass society, and a human orientation with one in which material things are more central to human existence. By extension, it is claimed that advertising has placed more emphasis on brand names as symbols than on the actual sum and substance of goods and services. This privileges simulacra over the 'real.' Likewise, advertising is said to have worked as a hegemonic force to the detriment of women, minorities, and other marginalized peoples (Faludi, 1991; Seiter, 1995). These are the major effects claims at the sociocultural level. Although there are many other derivations, they are largely subsumed by those categories outlined above.

The evidence for these claims is, however, rarely as strong as the accompanying rhetoric. Still, there are a few evidence-based conclusions. First, advertising has certainly made consumer culture possible. This may be the biggest advertising effect of all. To understand this, one has to appreciate advertising's role in advancing the practice of branding. Advertising made possible national brands, without which consumer culture would have died on the vine. Advertising projected brands and brand consciousness into national consciousness and into greater social centrality (Muniz and O'Guinn, 2001). Advertising made a brand-oriented society possible – perhaps inevitable. In 1850, few things were branded; by the end of the twentieth century, water and dirt were branded. The whole purpose of a brand is, in economic terms, to create greater inelasticity. A primary predictor of inelasticity is the consumer's belief that there are few acceptable substitutes. For example, when advertising made Ivory more than just soap, demand for Ivory became less elastic than demand for mere 'soap.' The same thing happened with beer, and soft drinks, and thousands of other products. So, clearly advertising lead to a proliferation of brands, which contributed to a more brand-oriented society. The brand is now a defining construct in contemporary consumer culture (Lindenman, 2010). This is an effect of advertising. While societies have always been involved with material culture, the massive extent to which branded culture emerged is quite clear, and not just a matter of degree. This is an advertising effect. Whether or not this has caused individuals to value things more than before is unknown, although it does seem clear that it probably produced more value for the explicitly (and highly marked) commercial object. Whether it caused individuals to value things more in relation to humans than previous generations did is a much harder case to make.

What then of advertising and hegemony? Advertising did and does provide support to modal social structures. Advertising, by its nature, is generally (but not always) a supporter of the status quo. Most researchers do not find advertising to be a great friend to progressive social movements, although it certainly has been from time to time. Unfortunately, many of the arguments regarding the hegemonic dynamics of advertising are hyperbolic and ahistorical (Scott, 2002). Further, the relationship between progressive movement, resistance, consumer agency, and advertising is far more complex than typically held (Muniz and O'Guinn, 2001). Consumer

resistance is now played out by the rejection of one brand (perhaps an ecologically friendly, green brand) over another brand. Belief in a 'star chamber' of corporate elite, or advertisers who control consumer's minds, is being thoroughly discredited (Scott, 2002) by social history research.

Advertising's effects in the areas of race and gender are far from simple, but have generally been negative. There is every reason to believe that narrow, pejorative, and stereotyped social portrayals have had detrimental effects when it comes to people of color (Grady, 2011). The same is no doubt true in the case of women, gays, and lesbians (Taylor et al., 2013). The evidence for this is more inferential than direct, but is consonant with empirical studies in other domains. We know that these groups were absent, stereotyped, or under-represented in typical advertising. Exactly what the effects are on self-perception and other types of perception is less well understood. We can assume it to be anything but positive, however.

In fact, social constructions of reality in general have been shown to be influenced by mass media and advertising portrayals of social reality (O'Guinn and Shrum, 1997). Recently, O'Guinn (unpublished manuscript) has shown that those exposed to a great deal of advertising on television believe there to be higher than actual rates of 'ad-problems' such as gingivitis, athlete's foot, bad breath, etc. There is good reason to believe that advertising has a significant impact in terms of simply making certain things more heavily represented in consumer's constructions of social reality.

Individual Effects

A considerable amount of advertising 'effects' research focuses on the individual. Most has been published in two academic fields: mass communication and marketing, typically from a psychological perspective.

In the 1940s researchers became interested in the effects of mass communication in general. Given the post-World War II consumption boom, advertising was of obvious relevance. The working model of mass communication was at that time a very simple direct effects model: message strikes audience member like a bullet. Experience with propaganda efforts in the war, the ascendancy of psychology in both the academic and larger social world, and outright naiveté led to this very simple notion of hypodermic needle-like effects (O'Guinn and Faber, 1991). There was a great deal of belief in the power of communications at a critical point in the social history of advertising. Exuberant communications researchers were going to wipe out bigotry, inform the electorate, and make things better in all aspects of life, including the realm of modern consumption. This belief was a popular and self-serving one for several groups, including the advertising industry itself.

It is not coincidental that the postwar period is literally drenched in Freudian and neo-Freudian notions. With the mind-control hysteria of the cold war, the prominence of psychology as a science and references to the subconscious mind led to a new exuberance in advertising research in both industry and academia. While the social scientists and public Freudians such as Ernest Dichter had major philosophical differences with one another, they both led to a psychological effects tradition in advertising research. To this day, discussion of advertising effects is influenced by the pervasive (and misguided) beliefs of the period.

There were, however, some exceptions. In communication, Katz (1957) proposed the 'two-step flow' model in which certain social actors and their communication networks were seen as more important than others in the spread of information and influence. This was the first time that any kind of social consciousness was included in the 'effects model' at all. This model held that other social actors mattered as much as the communication message itself, if not more. Since advertising was mass-mediated communication it was assumed to act in the same way. It was at about this time that another new field, marketing, discovered the communication literature. From the late 1950s through the mid-1970s, several marketing researchers went looking for the elusive generalized opinion leader, a person to whom advertising could be effectively targeted. This person would then pass commercial information through interpersonal channels to great effect. But alas, the search was fruitless: the generalized opinion leader could not be found, and most marketing research again eschewed the social for the more psychological 'message in a bottle' approach, at least for a while.

Another critical effects notion came along in the 1960s: the 'hierarchy of effects.' The basic idea was that effects of communication (in particular advertising) occurred along a hierarchy: from exposure to behavior (Colley, 1961). Each step along the way depended upon the step before. This helped to explain why advertising was generally inefficient, why it took so much to move consumers all the way to behavior from awareness. While a vast improvement compared with an undifferentiated bullet theory, it was still bound up in the idea of a linear and fairly inflexible progression of effects. But it inspired a great deal of advertising effects research. Generally speaking, research confirmed that not all ads lead to behavior. This was progress.

A significant trend in advertising effects research began in the mid-1970s. Known as the 'information processing' tradition, its orientation has been to study ads as the bearers of 'information,' which is then 'processed' by audience members. It was assumed that people actually did something with information gained from ads. This too was progress. These researchers held (at least implicitly) that underlying psychological processes would have to be understood in order to ultimately understand advertising's effects, and make them generalizable and predictable. Most of the earliest work in this tradition was heavily influenced by then-contemporary attitude theory (Fishbein and Ajzen, 1975), but later became increasingly more cognitive in orientation. Of all the things advertising does, its ability to get consumers to remember the brand, its name, and something good about it, has the longest research tradition. Interestingly, recall of advertising seems important in some instances, but completely useless in others. Keller (1993) demonstrates that advertisements are much better retrieved, and retrieved in a manner most desirable to the advertiser, when there is a carefully planned congruence between the advertisement itself and the point of purchase. The point of purchase should be rich with memory retrieval cues that are entirely consistent with elements found in the ad itself. This work is very important in that it explicitly links point of encoding and point of retrieval. This helps to explain why recall

of the actual ad seems important sometimes, and at other times, relatively worthless.

One model has dominated research in the psychological realm. It is the elaboration likelihood model (ELM) of Petty and Cacioppo (1986). This model says that there are two routes to persuasion: one peripheral and one direct. The direct route is marked by attention, consideration, engagement; in other words, 'elaboration.' The consumer engages arguments, or attempts at persuasion in a variety of ways, but generally takes them head-on, agrees with some, counter-argues others, etc. The peripheral route is just the opposite; there is little cognitive effort or engagement, and little motivation to process. In addition to these two routes, various cues were also assessed as either peripheral or direct. For example, source credibility, presenter attractiveness, or executional elements such as music, color, etc., are thought to be peripheral. Research emanating from the ELM has been encouraging, and generally supportive of the theory. Peripheral cues are at their best in situations where the consumer is less involved, has less at risk, and attention is low; central processing is most effective when the opposite is true. It is generally thought that long-term advertising effects are greatest when the direct route is engaged. In the long run, getting people to pay attention to ads seems to predict their greatest effect. While it is not exactly clear where emotions fit in the ELM, work by Edell and Burke (1993) demonstrates that emotions (particularly warm and upbeat ones) do influence the overall evaluation of the brand, and are recalled just as well as other types of information.

Another contribution from the effects literature is in the distinction between search attributes and experience attributes (Nelson, 1974; Wright and Lynch, 1995). Search attributes are objective pieces of consumer information: how many miles to the gallon, does the car come in red, how much horsepower does it have, etc. Experience attributes are those things that one can only really know via direct experience: does the engine sound good, did the seats feel comfortable, does the stereo sound good, etc? Wright and Lynch (1995) show that search attributes are actually better learned through exposure to advertising, while experience attributes are better learned through direct contact and use of the product or service. This effect is stronger under low involvement conditions than under high involvement. This finding is important because it has long been assumed that advertising was a fairly weak force compared to direct experience, in almost all cases. This is an important qualification of advertising effects. Similar findings by Edell and Burke (1986) show that consumer's pre-existing attitudes toward the brand have a great deal to do with the attitude-to-the-ad/attitude-to-the-brand connection, particularly as they mediate through motivation to process the ad.

Another interesting research area is the 'third person effect' (Davison, 1981). This work demonstrates that individuals attribute much greater power to advertising when asked about some other (third) person than himself or herself. In other words, they believe advertising to affect others much more than themselves. The effect is particularly strong when those doing the judging are higher in socioeconomic status (Atwood, 1994). So, relatively more affluent and educated people think that others, particularly poorer and less educated people, are more affected by advertising than they are. This effect has considerable implications for effects research in general, and public policy in particular. This work is typically carried out through surveys.

Special Audiences

Two audiences receive special attention in terms of advertising effects: young children (those under 12 years of age) and the elderly. The clearest findings are those reported by Roedder-John and Cole (1986). They find that significant processing difficulties exist in both children and the elderly. These are identified as 'memory-strategy' usage deficits, or strategies for the effective encoding and retrieval of stored information. These strategies are important in knowing how to effectively gain information from advertisements, and to defend oneself against some forms of deception (intentional or not). In addition, young children suffer from knowledge base deficits. They simply do not yet possess the requisite knowledge base to know how to interpret some advertisers' messages. The implication is that the effects of advertising on these populations may be significantly different than for others.

Going Forward

The arguments surrounding the relative worth of this literature are fairly typical philosophy of science ones. Experimentalists argue that the only way one is ever going to be able to understand the effects of advertising is to understand them within the tightly controlled confines of the laboratory, where all other noise is ostensibly screened out, and process is detected and discerned. More naturalistic researchers counter that advertising cannot be divorced from its social context and construction, and thus the pursuit of such effects is a comfortable conceit. Not too surprisingly, both sides make valid points. There are certain processes which would simply be hard, by their definition, to study outside a laboratory, at least where the detection of psychological process is concerned. On the other hand, things closer to actual behavior are more entangled, by their nature, in discourse, and social circumstance. Ethnographic work holds some promise. Actually watching people watch ads (at least on television) makes some degree of sense (Ritson and Elliott, 1999). Yet this work is limited to what people do with advertising content in their daily lives, or the social uses of advertising. We do not typically see ethnographic research at the point of exposure, or have any idea what is going on inside the audience member's head. Furthermore, there are all the familiar criticisms of ethnography: lack of control and ungeneralizable findings. Historical and textual methods also offer promise but it is certain that no single method is going to reveal enough about advertising effects on its own. The phenomenon is simply too large, too layered, and too multifaceted.

One of the problems beyond method is that advertising is simply not very important to most people, most of the time. As Klapper argues in his 1960 limited effects model: mass communication is only effective under two conditions: (1) where the communication is completely consonant and resonates with some social theme, or (2) in a total *tabula rasa* situation. In other words, it does two things very well: delivering

information and increasing knowledge. Beyond that it is an extremely weak force at the micro-individual level. The original VW Bug ads of the late 1950 and 1960s are good examples of the former. The VW advertising rode a developing wave of pop consumer counter-culture. The ads provided information consonant with this social movement. In other instances, literally nothing is known about specific goods or services, and advertising provides that information. A good example is the introduction of the compact disc player. In that instance advertising supplied consumers with essential information about something that was completely unknown to them. Advertising wrote useful information on a blank slate. But this is rare. Most of the time it is the noise in the background while we are preparing dinner, or the things between the segments of our television shows. Its effects are, by advertising's nature, difficult to pin down.

Abstract

Advertising is an industry that involves a three-way relationship between advertisers, their agencies, and the media. The history of this industry dates from the late nineteenth century in the industrialized countries, while the twentieth century has seen its growth on a global scale. Advertising's high visibility and pervasiveness has attracted much social criticism and successive analytic approaches over this time, with recent attention focusing on advertising's role in the formation of brands and social identities.

This article begins with the concept of advertising, defining it as a cultural industry carried out in agencies which mediate between the whole range of marketing practices pursued by advertisers, and the media which carry advertisements. The functional significance of this relation for the commercial media is then explained. A very brief history of advertising is outlined, with emphasis on the formative stages in the past century, with attention to the forces impelling the internationalization of the advertising industry. This leads to an outline of the rise of social criticism of advertising and its perceived effects, and governmental response in the form of regulation. A brief resume is given of past and present academic approaches to the study of advertising, which includes the analysis of advertisements themselves. The article concludes with some consideration of advertising within an anthropology of consumption and a postmodern commercial esthetic, with particular attention to advertising's role in branding in the age of social media.

Advertising is central to the study of media and the commercial applications of the social sciences. Not only does advertising revenue provide the major source of income for print and broadcast media owners, but also gives those media their characteristic look and sound, and orients their content toward the kind of audiences which advertisers want to reach. Advertising can be defined as a kind of cultural industry which connects the producers of consumer goods and services with potential markets through the diffusion of paid messages in the media. What is loosely referred to as advertising in everyday language is really just the most visible form of marketing, in which particular images become associated with branded goods and services. Within the industry, advertising is seen as just one part of what is now called 'integrated marketing communication.' Yet advertising is distinguished for being the imaginary dimension of what may be called the manufacturing–marketing–media complex of modern societies, the whole institutional structure of production and consumption.

Advertising as a Cultural Industry

Not all media depend upon the sale of their space and time for advertising – films, for example, don't carry advertising as such – and not all advertising depends upon the media for its diffusion. Some companies spend more on 'below the line' or nonadvertising forms of marketing communication, such as direct mail. However, in most countries, both the developed and the developing world, the largest advertisers of consumer goods and services, many of them global corporations, have determined the direction and character of print and broadcast media development because of their demand for the means ('media') which allow them to reach potential consumers. This is true regardless of whether the media are owned by private interests or the state, as was seen in the case of the rapid commercialization of television in Europe in the 1980 and 1990s.

Advertising is cultural in that it deals in images which give public expression to selected social ideals and aspirations, but it is also an industry because of its crucial intermediary role in the manufacturing–marketing–media complex. It was in this sense that Raymond Williams called it 'the official art of modern capitalist society' (1980: p. 184).

The intermediary role is carried out by advertising agencies (*see* Advertising Agencies). These 'agents' produce and place advertising for their 'clients,' the consumer goods or service companies who are the actual advertisers. However, while the clients pay the agencies for their services, agencies also derive income directly or indirectly from the media in the form of a sales commission paid in consideration of the media space and time, traditionally newspaper pages or television 'spots,' which the agencies purchase on behalf of their clients.

This is the crux of the manufacturing–marketing–media complex referred to above. Indeed, this form of dealing in media space and time was the origin of advertising agencies as a form of business in the later nineteenth century, and continues as a fundamental aspect of the industry today. The judicious purchase of media space and time is part of the range of functions routinely performed for clients by 'full-service' agencies, while there have emerged specialized agencies which deal in such media purchasing alone, known as 'media agencies.'

Looking at the complex of relations between advertisers, agencies, and media from the point of view of the media as an institution, it becomes evident that in most countries, the dominant print and broadcast media are 'commercial,' as distinct from government-funded or nonprofit media. This means that the measurement of readerships and audiences becomes an issue for advertisers, as they want to be sure that their advertisements are reaching the kind and range of the prospective consumers they seek (*see* Audience Measurement).

For their part, the media must seek to attract those prospective consumers as readers or viewers, and this becomes the basis for the kind of content they provide.

While this relation is easiest to observe in the case of broadcast television and its constant striving to offer programs which can attract the largest audiences, mostly for the benefit of national advertisers of packaged consumer goods, to many advertisers, the kind of audience can be more important than the size. The agency's expertise in the choice of medium for the client is a key element in their mediation of the process of fitting people to products. Thus, while the broad appeal of television content might reflect a relatively undifferentiated 'mass' nationally-networked audience-market, other media such as prestige newspapers and special interest magazines are supported more by advertisers who are interested in reaching only affluent consumers or niche markets, respectively. Notably, the advent of the internet has given advertisers an unprecedented medium through which to reach ever more closely targeted markets, especially through social networking sites such as Facebook.

All of these connections to the media industries are of most interest to political economists of the media, while social science and cultural studies more generally have been more concerned with the cultural output of advertising agencies, in the form of the marketing campaigns which they devise for their clients, and the actual advertisements which they produce. Here once again, full-service agencies provide various other marketing activities, including market research, a major form in which social science methods are applied for commercial purposes. However, it is the 'creative' side of the agencies' work, including that of specialist creative 'hot shops,' which gives advertising its cultural significance.

The Development of Advertising

Advertising has its origins not just in the sale of space and time, but in its role of providing distinct identities to branded goods and services. It arises in the USA and the UK around the late nineteenth century when packaged household products began to replace generic goods bought in bulk: Pears rather than soap, to name one of the world's very oldest brands. By giving brands a particular character and often a logo or slogan to make them recognizable, advertising contributed to the national, and later the international, expansion of brands such as Lipton, Gillette, Kodak, and Ford. By the 1920s, advertising was forging an alliance with what were then the still fairly new social and behavioral sciences, drawing on sociological techniques for market research, and devising psychological appeals for advertisements themselves.

Also around this time, some of the longest-established US agencies began to expand overseas. For example, J. Walter Thompson upgraded its sales office in London, while McCann-Erickson opened branches in Latin America. In both cases, this expansion was initiated at the request of large clients whose brands they handled in the USA, and that wanted similar advertising services provided for them on a 'common account' basis in the foreign markets they were opening up. US brands such as Coca-Cola thus became known worldwide.

However, the most important period for the internationalization of the advertising industry was the period after World War II. Apart from this being the era in which many US companies transformed themselves into multinational corporations, it was also the time when television was a new medium being adopted by one country after another around the world. Because the US agencies had their common account agreements with their clients from their home market as well as some experience with television, they were able to quickly dominate the advertising industries of those countries they entered.

Indeed, by the 1970s, this movement had provoked some resistance, and US advertising agencies became one of the targets of the rhetoric against 'cultural imperialism' in that decade. Subsequent expansion then had to proceed more through joint ventures in conjunction with national agencies. However, a more elaborate pattern emerged in the 1980s, particularly with the growth of certain British agencies, notably Saatchi & Saatchi. No longer was the worldwide advertising industry defined by a fairly simple conflict between US-based multinationals versus the various national interests, but there were more complex tendencies emerging.

Most significantly, what the British agencies did was to keep their new US acquisitions intact and incorporate them into 'megagroup' structures, a strategy already undertaken by McCann-Erickson following its merger with SSC&B Lintas. This was a way of dealing with 'client conflicts,' for example, British Airways could be handled by Saatchi & Saatchi, while other airline accounts could be assigned to different agencies in the same group without fear of marketing secrets being leaked from one to the other (Sinclair, 2012). Apart from this kind of integrated concentration in the English-speaking world, substantial French and Japanese groups have formed, so that there is a trend to the interpenetration of national markets and of world-regional markets, including joint ventures in culturally difficult markets such as China and India. These trends became more marked with the globalization of the 1990s and 2000s (*see* International Advertising). Also worth noting has been the tendency for the global megagroups to incorporate under their umbrella companies in related marketing communication fields such as public relations, as well as advertising agencies in more specialized fields, notably internet advertising.

The advent of the internet has become a considerable challenge to the traditional, quite settled relationships within the manufacturing–marketing–media complex. In particular, the unprecedented rise of search advertising and the dominance of this field by Google has meant that advertisers can now bypass the agencies and place their advertising directly with Google or the other search engines. Internet advertising has shown very rapid growth, particularly at the expense of print media. The largest advertisers globally, however, continue to invest the bulk of their expenditure in television.

Globalization has had controversial effects upon the content of advertising. While some agencies advocate the standardization of advertising campaigns throughout the world ('one sight, one sound, one sell'), others argue for what the Sony Corporation calls the 'glocalization' of both products and their marketing, that is, adapting them in accordance with the cultural differences evident between the various national

markets. In practice, services such as credit cards or airlines appear to benefit from global advertising, but goods such as packaged foods do not (Sinclair, 2012).

The Critique of Advertising

As the advertising industry has been consolidating itself at its most intensive level of globalization ever, it is ironic that the social critique which accompanied it during its previous decades of expansion has become relatively diminished. However, for most of the later part of the twentieth century, advertising was subject to considerable critique from various quarters of society, and on economic as well as cultural grounds, so it is worth reviewing the terms of the debate and the sources of criticism.

It has been the critics of advertising who have made the most elaborate claims about its economic importance. Marxist and liberal critics alike have argued that advertising creates and controls demand, thus attributing to it a key function in the perpetuation of consumer capitalism. Certainly, modern marketing gives producers a wide range of sophisticated strategies and techniques, but advertising is only one element among them. Furthermore, the fact that the vast majority of new products still fail when they are introduced to the market suggests that there is no one in control of demand.

Another economic criticism of advertising is that it adds to the price of goods and services, because advertising costs are real costs which are passed on to the consumer. The rebuttal is that, because 'advertising is the shortest distance between producer and consumer,' to quote J. Walter Thompson, it rationalizes the distribution process, generating only small costs which are spread easily over the large volumes of production which advertising helps to make possible.

The defenders of advertising argue that it is necessary to maintain competition, and that if producers do not advertise to maintain their market share, they will be driven out by their competitors, creating oligopolies, or markets dominated by very few producers. However, it follows that advertising is also a barrier against the entry of new players, who must necessarily be able to establish high levels of advertising from the beginning. This favors the 'market power' of the existing producers, so advertising would appear to favor oligopolistic markets.

In practice, it is evident that some of the industries which advertise the most heavily, such as packaged foods, or household and personal cleaning products, do indeed have tendencies to oligopolistic concentration. Furthermore, it is worth noting that such oligopolies tend to maintain themselves not by the mass advertising of just one product line, but by product differentiation: for example, different shampoos for different types of hair. Advertising is implicated here because of its crucial role in branding, 'positioning,' and otherwise creating apparent differences between products for different types of consumers.

The connection between the ideological and the cultural dimensions of advertising is achieved most fully in the Marxist critique, where advertising is seen to perform ideological 'functions' which reproduce the capitalist system as a whole. In the USA, Stuart Ewen argued that department store owners and other ideologues of capitalism in the 1920s embarked on a "project of ideological consumerization" (1976: p. 207) to draw working people into compliance with capitalism. More recent theory would see this as part of the 'pact' between capital and labor which stabilized the growth of capitalism in the first part of the century, the age of 'Fordism' (Arvidsson, 2006). In the UK, Marxist critics such as Raymond Williams (1980) were influenced by a British tradition of social critique which denounced advertising on moral grounds, not so much because of its materialist values, but more because of its persuasive appeals and irrational associations. Other Western Marxists took the view that advertising was an agent of 'false consciousness,' lulling the masses into acceptance of their place in an unjust social order.

The Marxists have not been isolated in the critique of advertising, however. Liberal critics of capitalism in the USA in the 1950s, a formative period in the history of the manufacturing–marketing–media complex, were read throughout the English-speaking world; thanks to the innovation and spread of paperback publishing at that time. Particularly in the context of the Cold War and popular fears about ideological 'brainwashing,' exposés of 'motivational analysis,' and the 'manipulation' of symbolic meanings in advertising, notably Vance Packard's *The Hidden Persuaders*, first published in 1957, found a ready audience. The following year, J.K. Galbraith's *The Affluent Society* came out criticizing the US economy for the way it produced the very needs which its goods were intended to satisfy.

The twentieth century's last phase in the social criticism of advertising came from the women's movement, beginning in the 1970s. Advertising was a major public cultural arena which women cited as evidence of the social processes through which sex-roles were represented and reproduced through 'stereotyping.' In particular, advertising was seen to perpetuate women in subordinate domestic roles, at the kitchen sink in detergent advertisements, for example, or alternatively, as sexual objects presenting themselves for the pleasure of the male gaze. Women's criticism of the 'sexism' of their representations in advertising was sustained into the 1980s, often with accompanying activism, even as advertising began more to represent the 'new' independent woman. Since the 1990s, feminist critique has become largely absorbed into a broader academic approach to consumer culture in general, but gender remains an issue, seen in concerns over the impact of advertising on body image, for example.

In addition to the specific economic effects attributed to advertising, as outlined earlier, each of these classic phases of social criticism focuses on one of advertising's alleged cultural effects – that advertising has an ideological role in papering over social inequalities, that it creates false and irrational needs, and that it subordinates and degrades women. As well, there are other social concerns, with a similar perception of its power, which legitimize a public interest in the regulation of advertising – most famously on health issues, notably the question of tobacco advertising, and more recently, advertising's role in childhood obesity (*see* Advertising, Control of).

Beyond academic critique, advertising attracts some form of regulation in all countries, but with great variation, particularly in the ratio of self-regulation by the industry itself, as compared with government-prescribed regulation. Apart from the considerable cultural differences about what is acceptable

in advertising images, advertising regulation typically restricts the type of product which may be advertised, such as alcohol and tobacco; the media which may be used, and at what times; the extent of product claims and invidious 'comparative' advertising; and in some cases, the use of foreign-produced advertisements (Frith and Mueller, 2003).

No doubt the capacity of advertising to exert social influence is greatly overestimated, and its structure and processes much misunderstood, but even in an age of 'deregulation,' most governments are reluctant to surrender too much of their control over advertising. For their part, the advertising interests seek to defend themselves from government intervention by developing voluntary, self-regulatory codes in the most controversial areas. An interesting and current case in point is the environmental movement's critique of advertising, which, they say, promotes consumer demand for products which generate waste and degrade the environment. Advertisers in response have clamored to assert their 'green' credentials, sufficiently to keep governments at bay, although not to convince their critics (Smart, 2010).

Advertising in Social Theory

The social criticisms of advertising referred to in the previous section, arising from liberalism, Marxism, and feminism, are grounded not just in those various social and intellectual movements as such, but also in the considerable academic theorization and research which they have generated in the social sciences.

While it would be less true of the USA than the UK, Canada, and Australia, Marxism provided the dominant paradigm in cultural studies and much social science, particularly sociology, from the mid-1970s until at least the end of the 1980s. This was a 'Western' Marxism in which there were two main trends: one toward 'political economy,' which emphasized the ownership, control, and functioning of the economic structure of capitalism, and the other toward the cultural analysis of role of ideology in maintaining the system as a whole. In both trends, but particularly the latter and more influential way of thinking, advertising was seen to have a crucial role to play in stabilizing a society which would otherwise be torn apart by its own contradictions. Following the French Marxist structuralist philosopher Louis Althusser, Marxist social theory in the 1980s thus shifted its analytical focus away from the economic structure as the basis for capitalist society, and toward ideological reproduction – the representational and signifying practices of capitalist culture, including advertising.

This tendency in cultural Marxism found common cause with semiological structuralism (*see* Semiotics), derived from Ferdinand de Saussure, but mobilized most famously with regard to advertising by Roland Barthes (1977). In this approach, advertisements themselves became the main object of analysis, such that the emphasis was upon how the various meaningful elements, or the 'signifiers' in an advertisement, related to each other so as to produce the meaning of the advertisement as a whole (*see* Advertising and Advertisements). This is a qualitative, interpretive approach which contrasts with the quantitative method of 'content analysis.' The latter, with its roots in US behaviorism, nevertheless can be applied in complementary and productive ways in conjunction with semiological analysis.

Along with Marxist and semiological structuralism there was a significant contribution from anthropological structuralism, stemming from Claude Lévi-Strauss. These strands were all brought together, along with feminism and the psychoanalytic development theory of Lacan, in Judith Williamson's *Decoding Advertisements*, still one of the most definitive books ever on the analysis of advertisements (Williamson, 1978). She provided a coherent fusion of these theories, and applied them in the qualitative analysis of scores of magazine display advertisements, to evince such processes as 'interpellation' and the invocation of ideological 'referent systems' in the interpretation of advertisements. Apart from Williamson's application of Lévi-Strauss's theory of 'totemism' to explain how certain kinds of people become associated with particular products in advertising, such as the 'Pepsi generation,' anthropological structuralism provides a way of understanding how goods become endowed with cultural significance through their position in a total system of meaning. Advertising visibly contributes to this process of giving meaning to goods, but by no means exclusively. The process is socially mediated. For example, of several different international brands of sportswear advertised in similar ways, it will be the peer group that decides which of them is to be the preferred 'cool' brand in any given locality.

The same relational quality of the cultural meaning of goods is also found in the post-structuralist contribution of Jean Baudrillard (1981). In his view, capitalist social structure was the source of needs as well as of the meaning of goods, and like certain of the liberal and Marxist critics of advertising cited above, Baudrillard saw the rise of consumer capitalism as a device by which the system avoided the need to redistribute its wealth. Thus, class differences were concealed beneath an apparent democracy of consumption, a connection which is lost in the bewildering and endless display of signification, he said.

With the advent of post-structuralism and postmodernism, the diversification of feminism, and the eclipse of Marxism, there was much less critical attention paid to advertising as such during the 1990s. Rather, although traditional press and magazine display advertisements, television commercials, and billboards continued to provide the examples of postmodern visual culture which were cited, theory and research from the 1990s onward see advertising in a broader and much more theorized context. This is even wider than the manufacturing–marketing–media complex described above. Thus, for Wernick (1991), advertising was just a part of 'the promotional condition of contemporary culture,' which went beyond the marketing of commercial goods and services to include the mode of public communication now embraced by all major social institutions, from political parties to universities, and also found in the presentation of one's own self.

In ways like this, theory and research were moving beyond the study of advertising as such, and taking a 'cultural turn' toward the analysis of consumer culture in general. Not only has this shift encouraged attention to the role of hitherto-neglected institutions such as the department store and the supermarket, but also to transformations in work, domestic life, and cultural identities, insofar as these have become expressed and commodified in terms of consumer goods. This

agenda in turn has given rise to studies of how specific groups have been constructed, represented, and appealed to by marketing strategies, and of how they have responded. Most recently, because advertising as an institution is so much an agent of commercial culture, it has become an area of particular interest to the 'cultural economy' school of thought in Britain (McFall, 2004).

Such lines of investigation have been a refreshing corrective to the preponderance of attention previously given to the content of advertisements themselves, made without regard to their audiences, which hitherto characterized most theorization and research about advertising. Furthermore, the new approaches have provided some insight into the 'reflexive modernization' with which consuming audiences have been seen to regard media and consumption in the era of globalization (Lash and Urry, 1994). This reflexiveness entails a postmodern esthetic in which consumers express themselves as individual subjects by means of how they mobilize their knowledge of the codes of meaning which goods carry, codes which are partly bestowed by the images in advertising, marketing, and the media, but which become embedded within popular culture. Clearly, this cultural relation of mediated images and their expressive use cannot be understood by analysis of the images alone. Writers such as Klein (2001) have pointed to the way in which advertising observes and exploits movements in popular culture, a process in which advertising creative staff may be personally involved as 'cultural intermediaries' (McFall, 2004). Ethnographic studies, such as that of Nixon (2003) within agencies in Britain, confirm how advertising personnel themselves may be participants in the subcultures which they draw upon in creating their advertisements. Other research shows how advertising agency personnel are also actively engaged in perpetuating the mythic status of advertising itself (Cronin, 2004).

As 'advertising' as an object of study has become more elusive in an age of media fragmentation and audience segmentation, the study of branding in particular has served to refocus upon the relationship between persons and goods in the age of new media. More than uniquely identifying a product or its manufacturer, branding enables products to acquire cultural meanings, such as status positioning; associations with certain lifestyles; and even something like their own personalities (Moor, 2007). Arvidsson has argued that consumers, rather than being the passive dupes of advertisers, actually participate in the making of a brand, albeit unequally: the value of a brand ultimately derives from the 'meaning-making activity' of consumers (2006). Advertisers pick up on these meanings and exploit them by associating them with particular products and services. The advent of the internet has given advertisers a means through which they can tap meaning-making as never before, for instance by drawing upon user-generated content, such as the one that has occurred in the United States for Super Bowl advertising, or by strategically placing videos on the internet in the hope they will 'go viral'; that is, users will want to send them on to each other. On the other hand, the advertisers of brands which are awkward or inauthentic in their appeals to users run the risk of 'culture jamming,' that is, being ridiculed by the same means, such as having lampooned versions of their advertisements being circulated over social media. However, the internet also enables online behavioral advertising, which allows advertisers to target individuals who have readily surrendered information about their tastes and interests on their favorite social networking web sites, thus identifying themselves as having an affinity with particular brands. The quest for individualization and authenticity in consumption is thus seen to be harnessed into forms of 'work' which consumers carry out for advertisers, because of the way in which consumers unwittingly signal lifestyle and subcultural trends to advertisers (Hearn, 2008).

Finally, as far as contemporary studies of the manufacturing–marketing–media complex are concerned, the challenges for theory and research are to keep pace with globalization, to comprehend its complexities, and to monitor the new relationships and business models which are forming between marketing and media in response to the growth of new technologies. Of particular interest is the role of advertising in cultivating huge new markets among the emergent middle classes of countries as diverse as Brazil, Russia, India, and China, and the question of whether those markets will be incorporated into the manufacturing–marketing–media complex as we have known it. On the technology front, the apparent gulf between 'new' and 'old,' or 'social' and 'mass' media, respectively, has been bridged through advertising campaigns increasingly being mounted on a 'cross-platform' basis. Mobile media which give access to the internet, notably 'smart' cellphones and tablets, represent a new frontier, and have opened up the unprecedented targeting of advertising in accordance with a user's precise physical location.

Advocacy and Equity Planning

Abstract

Until recently, most American city planners dealt solely with the physical city. But an alternative planning practice dealing with social equity has existed since the early 1900s, at the margins of the profession. These 'equity or advocacy' planners flourished during times of crisis, which bring forward the reform elements of the American state. They have had an impact on the profession. At the end of the twentieth century, American city planning was more sensitive and collaborative than it had been earlier.

Advocacy or equity planners are professional city planners who deal with the physical city while also trying to redistribute resources, political power, and participation toward disadvantaged urban populations. Their practice goes back to the early twentieth century and includes examples of tenement housing reform, low-income housing, common ownership of land, national resource planning, citizen participation, and linkage arrangements between downtown and poor neighborhoods. Through the years, leading advocacy/equity planners include Benjamin C. Marsh, Catherine Bauer, and Paul Davidoff. Although advocacy/equity planners often struggle against a market-oriented society, they have succeeded to an extent in liberalizing American urban planning. They have not, however, overcome persistent urban poverty, racial segregation, or growing economic disparities between city and suburb.

Until recently, most American city planners dealt solely with the physical city. They designed streets, parks, and boulevards; made plans for the way land was to be used in the community; and prepared regulations to control the use of land. Advocacy or equity planners are those professional planners who not only deal with the physical aspects of the community but who, in their day-to-day practice, also deliberately try to move resources, political power, and political participation toward the lower income, disadvantaged populations of their cities. They are called 'advocacy' or 'equity' planners because they seek greater equity among different groups as a result of their work. Where the work of most city planners is rarely consciously redistributive, advocacy or equity planners often conceive the potential contribution of planning in broad economic and social terms and try to provide for a downward redistribution of resources and political participation in order to create a more just and democratic society.

Many observers place the birth of advocacy and equity planning in the decade of the 1960s when crowds were in the streets of American cities protesting the wholesale demolitions and displacements caused by urban renewal and the interstate highway program. These traumatic events and the antiwar and civil rights movements, which occurred at about the same time, challenged the belief in top–down planning by benign, value-free experts and created a demand for more social planning based on grassroots involvement. The events of the 1960s provided great support for advocacy and equity planning, but actually, an alternative planning practice oriented toward equity considerations had its roots in the turn of the twentieth century.

To begin this exploration into recent history, one must go back to the period between approximately 1880 and 1915, known as the Progressive Era, a time when the respectable urban bourgeois discovered the slum city festering beneath their urban world. At the time, America was rapidly changing from an agricultural to an industrial society. American farmers, forced off their homesteads, joined European immigrants flooding into industrial cities. The largest cities, as centers of manufacturing, exchange, and distribution, had grown most explosively without proper planning or the means to regulate growth. They became choked with slums built to house immigrant workers (Riis, 1971). The slums, in cities like New York and Chicago, became such breeding grounds of disease, crime, and human misery that efforts at reform were introduced by civic and political leaders. It was this revulsion against the slum and the fear of revolutionary social unrest that brought housing reform and the social aspects of urbanism into modern urban planning. Progressive leaders believed that such dismal conditions could not wait on beneficent forces, but could be corrected by diligent and scientific health and housing policies.

The settlement house movement was one of their first efforts at neighborhood improvement. In the poor, immigrant neighborhoods of dozens of major cities, settlement houses like Hull House in Chicago, Henry Street Settlement in New York, and South End House in Boston were established. These were mostly staffed by middle- or upper-class social workers who taught the English language and domestic arts to immigrants, lobbied city government for more neighborhood parks and other public facilities, and pressed for effective tenement housing reform. In the process, the settlement house workers hoped to improve housing and neighborhood conditions, and 'Americanize' the new immigrants. They were not urban planners but, then, advocacy for parks, better housing, and other improvements in the slums helped provide the reform underpinning for the nascent city planning profession.

Three typical progressive era reformers were Mary Kingsbury Simkhovitch, Benjamin C. Marsh, and Alice Constance Austin. Simkhovitch pursued a wide range of social justice issues, including women's suffrage, economic reform, and progressive politics. After establishing Greenwich House in New York City, she worked to improve housing density and building-code

laws. During the 1930s, Simkhovitch performed her most important work when she helped draft the Wagner–Steagall Housing Act of 1937, providing federal participation in low-income housing for the first time in America.

Benjamin C. Marsh was the Secretary of the Committee on Congestion of Population, a prestigious committee formed in 1907 by 37 civic and philanthropic organizations to study, publicize, and promote programs to relieve the problems of excessive massing of people in New York City. Marsh widely traveled and was strongly impressed by European city planning, especially by the ideas of the Englishman Ebenezer Howard (Howard, 1965). Howard, who loathed the industrial city with its filth and overcrowding, proposed a scheme of land development based on population dispersion into a regional pattern of small, self-contained cities. These garden cities would enjoy all the advantages of the core city including nearby jobs in industry, higher wages, and social opportunities, while also enjoying the benefits of the countryside with low rents, fresh air, agricultural gardens, and cooperative arrangements to maintain the land. A central feature of Howard's scheme included the common ownership of land so that the unearned increments in land values could be recaptured for the benefit of the entire community. Howard's sweeping planning ideas were enthusiastically adopted by Marsh, for whom city planning was a holy war against predatory forces, especially real estate speculators. Marsh's energetic career as a skilled organizer and publicist of planning issues made the city planning movement better known nationally and more socially responsive. His small paperback book, *An Introduction to City Planning* (1909), set the stage for the First National Conference on City Planning and the Problems of Congestion convened in Washington, DC, in 1909, which marks the formal birth of American city planning.

Alice Constance Austin also used Ebenezer Howard's new town ideas as examples of good city planning when she assumed the role of city planner and architect in 1915 for the partially built socialist city of Llano del Rio in California (Hayden, 1976). Austin also learned from Patrick Geddes, a Scottish biologist, who drew up dozens of town plans in India and elsewhere, based on a cooperative model of city evolution. Austin's debt to Howard's garden city is reflected in her organization of the city of Llano del Rio, with its 'crystal palace'-like central buildings and its boulevards and street system. Her approach to building design was, however, distinctly feminist. Here, Austin proposed not only private gardens, but also communal kitchens and laundries to liberate women from drudgery.

Early American planners, most of whom were architects and engineers, believed that the way to bring the city under control was to reduce congestion, make physical development more attractive, and control the flow of traffic. They thought planning and zoning examples from Europe, especially from Germany and the United Kingdom, provided good direction. But, although early American planners used European models to define good planning, in one key respect the American approach diverged sharply from the European experience. In France, Germany, and the United Kingdom, the answer to the provision of low-income housing was government support; in the United States, such support was decisively rejected. Lawrence Veiller, author of the New York City tenement-house legislation of 1901 who later founded the National Housing Association, maintained that only local government should concern itself with housing, but only to enforce local building regulations (Scott, 1995). Otherwise, private benevolence could do the job. In Veiller's view, it was proper for local government to clear slums, but not to rehouse the displaced families.

A small group of visionaries rejected the physical determinism of most early planners. The Regional Planning Association of America (RPAA), formed in 1923, included such planning luminaries as Catherine Bauer, Stuart Chase, Benton MacKaye, Lewis Mumford, Clarence Stein, and Henry Wright. They believed in planning entire regions to achieve social objectives. Following the ideas of Howard and Geddes, RPAA members expounded their vision of small, self-sufficient communities scattered through regions in ecological balance with rich natural resources. In the distribution of electric power by regional grids and the speed of the automobile and truck, they saw new tools for rehabilitating declining urban neighborhoods and liberating large cities from congestion and waste.

The thinking and writing of RPAA's members was influential beyond their small numbers. Their ideas on regional planning and environmental conservation led in the 1930s to the creation of the Tennessee Valley Authority (TVA), the Civilian Conservation Corps, the 14-state Appalachian Trail, and the regional studies of the National Resources Planning Board. RPAA member Benton MacKaye, who conceived the Appalachian Trail, was clearly one of the founders of the modern environmental movement.

RPAA's main practical experiment, however, was only a mixed success (Birch, 1980). It was the garden city–inspired development of Radburn, in Fairlawn, New Jersey, constructed in 1928 using Ebenezer Howard's ideas, but adjusted to American customs and laws. The elements of Radburn include the 'superblock,' the cul-de-sac and narrow loop lanes for residential traffic, the clustering of housing around large areas of parkland in common ownership, and the separation of vehicular and pedestrian traffic. Radburn also provided day care for working mothers and similar social services, as well as a community organization to administer commonly held land. Although Radburn has had an important influence on American planning thought and design, it failed to realize its sponsor's hopes of becoming a completely self-sustained community. It has now been swallowed up as part of northern New Jersey's amorphous sprawl.

By the time America emerged from World War I, the Progressive Era had lost much of its momentum. City planning, slum clearance, and housing reform, which had been part of the upsurge of reform, now suffered from a weakening of the liberal impulse. RPAA member Frederick L. Ackerman attacked the profession for no longer being concerned about "the causes which give rise to the existing maladjustment" in cities. America had maladjusted communities, he said, because planners declined to interfere with "the right of the individual to use the community as a machine for procuring individual profits and benefits, without regard to what happens to the community" (Ackerman, 1919).

Urban planning and especially social or equity planning lagged during the 1920s with 'the business of America was business,' but the Great Depression and the New Deal administration of Franklin D. Roosevelt (FDR) brought both back. FDR believed that the power of government should be used to restore misused land, harness wasted water, and revitalize despondent human beings. In his first term, FDR enacted legislation authorizing the widest application of planning yet proposed, including the TVA and the Resettlement Administration. By Executive Order, FDR also established the National Planning Board, later the National Resources Planning Board.

The National Resources Planning Board was America's first effort at national planning. The Board advised the Department of the Interior on regional planning, land and water conservation, and issues of social insurance and poverty. As Secretary of the Interior, Harold L. Ickes, told city planners and members of the American Civic Association in 1933, "long after the necessity for stimulating industry … shall be a thing of the past, national planning will go on as a permanent Government institution." However, the Board was resented by many old-line federal agencies like the Army Corps of Engineers who chafed under the Board's attempts to coordinate their projects, and by conservative Congressmen who feared that the agency was promoting foreign, socialist schemes. As a result, and to wide and dolorous lamentation among planners, Congress abolished the National Resources Planning Board in August 1943.

The Resettlement Administration, established in 1935 under the leadership of Rexford G. Tugwell, suffered a similar fate. Tugwell, who once proposed that the (US) Constitution be changed to include planning as a fourth power of government, immediately embarked on an effort to improve living conditions for working people in metropolitan areas. He seized on the idea of the English suburban garden village, but adapted the concept to the American situation. The towns built by the Resettlement Administration were called Greenbelt Towns. Originally, Tugwell's staff identified eight metropolitan areas where new towns were to be built, but funding limitations narrowed the choices to three areas: Greendale, Wisconsin near Milwaukee; Greenhills, Ohio near Cincinnati; and Greenbelt, Maryland near Washington, DC. The three towns, all examples of high-quality planning, featured small homes in a well-planned garden setting and housed about 2100 families in all. The distinctive feature of all three towns was the surrounding greenbelt protecting the towns from outside encroachment. The residents, largely industrial workers, were provided an opportunity to live in a low-cost, but far superior environment than they were used to. As a demonstration, the Greenbelt Towns made clear that superior alternatives existed to haphazard speculative sprawl. Unfortunately, before the Resettlement Administration could expand the three towns and build two others that were on the drafting table, Congress abolished the agency in June 1938. It was left to post–World War II British planners to build a substantial new towns program, while the United States had to content itself with the three Greenbelt towns and a few commercial initiatives including Reston, Virginia, and Columbia, Maryland.

FDR's New Deal also produced the first major intervention in the field of low-rent housing. Pushed vigorously by RPAA member Catherine Bauer and others, the administration passed into law the Housing Act of 1937, which provided low-rent housing for the deserving working poor. For the first time, the federal government would provide support for the capital costs of public housing construction; tenant rents were to take care of subsequent operating and maintenance costs. Later, in 1949 and 1954, Congress returned to the public housing issue and emerged with a commitment to more low-income housing. But Congress also made a larger commitment to urban renewal, which ultimately demolished more low-income housing close to the city core than was built. The scale of demolition and forced relocation was large; a study by the National Association of Home Builders estimated that the total housing demolition by all public programs between 1950 and 1968 amounted to 2.38 million units. These units were disproportionately the homes of poor and near-poor black families.

Ultimately, a revolt broke out against these excesses. Within an astonishingly short time, this revolt caused an almost complete inversion of almost every basic value in American planning practice. Influential critics Jane Jacobs (1961) and Herbert Gans (1962) spoke for the preservation of older urban neighborhoods, as they pointed out that planners implementing the urban renewal program were thoughtlessly destroying valuable housing and irreplaceable social networks while providing opportunities for profitable real estate investments. The opposition to urban renewal coincided with the civil rights movement, and racial riots tore through the cities revealing just how little the planning process had done for the poor. Opposition to the war in Vietnam, and with it the Pentagon style of planning by top–down, bureaucratic experts, was at its peak. There was now a deep distrust of professional expertise and there was a demand for advocacy and equity planning based on grassroots involvement.

Paul Davidoff, a lawyer, planner, and educator, made the most substantial contribution to the concept of advocacy planning (Davidoff, 1965). He argued that advocacy could reinvigorate planning in three ways: by broadening public debate and participation, by sharpening the skills of planners who would have to defend their choices, and by shifting the focus of planning from the purely physical to social and economic priorities. The essence of advocacy planning is the encouragement of alternative plans by all groups holding special values about the future of their communities. Advocacy planning would supplement the one, official city plan with alternative plans by Liberals, Conservatives, Democrats, and Republicans and other groups, but the emphasis would be on professional planning services for the poor, the black, and the underprivileged. Using legal analogies, the merits of these alternative plans were to be debated and the best plan would emerge from the debate. Davidoff's ideas were taken up by planning practitioners and educators with a strong cumulative effect.

During the 1960s advocacy planning organizations serving minorities, poor, and working-class whites were formed in many American cities (Heskin, 1980). Exemplars were Architects Renewal Committee of Harlem in New York City (1964), Urban Planning Aids in Boston (1967), and the Community Design Center in San Francisco (1967). The effectiveness of these grassroots organizations was limited

given their inadequate resources and often defensive strategies, but they signaled a new diversity. A national organization called Planners for Equal Opportunity was established in the 1960s and in 1975, under the leadership of advocate planner Chester Hartman; it continued as Planner's Network. By 1999, Planner's Network represented over 800 planners and academics concerned with social and economic justice. By the 1970s, the American Planning Association (APA), whose journal carried virtually no discussion of racial issues prior to 1970, had modified its Code of Ethics and Professional Responsibility to reflect concern for vulnerable populations: "A planner shall seek to expand choice and opportunity for all persons, recognizing a special responsibility to plan for the needs of disadvantaged groups and persons …"

How deep the commitment was to rank and file planning practitioners still must be determined, however. In 2005, APA/American Institute of Certified Planners amended its Code of Ethics and Professional Responsibility by moving its clause on "special responsibility to plan for the needs of disadvantaged groups" from the rules of conduct for which planners can be held accountable and subject to disciplinary action to a merely aspirational principle that cannot be the subject of an ethical misconduct charge (APA/AICP, 2005). This change was a major setback. Although the clause was difficult to enforce legally, which was the reason for the change, it served as a guide and inspiration for planners who were trying to shape their practice in a more equity-oriented direction.

Davidoff's writings on choice theory were important intellectual contributions to planning theory and they make him the preeminent symbol of progressive planning. They make perhaps the most persuasive argument on how a planner might reconcile professionalism with political engagement.

But Davidoff's substantial contributions to planning theory and practice were matched by his efforts at institutional innovation. He realized that from 1950 onward, the overwhelming preponderance of growth in population, jobs, and economic investment was not in America's cities but in the suburbs. Because of racial discrimination and exclusionary land use controls, blacks were being shut away from the benefits of suburban growth. In response, Davidoff founded Suburban Action, a nonprofit institute for research, litigation, and advocate planning services within metropolitan regions (Davidoff et al., 1970). Suburban Action used its resources to legally challenge restrictive zoning and land use controls in the suburbs and enlarge suburban opportunities for the black and poor.

Davidoff's special concerns for the disadvantaged were also adopted in some official city planning agencies within local government. One of these was in Cleveland, Ohio, where planning director Norman Krumholz and a core staff of progressive planners developed a system of values and strategies in the 1970s that came to be called 'equity planning.' The central theme adopted by the Cleveland planners was contained in this statement: "In the context of limited resources, first and priority attention should be given to the task of promoting wider choices for those Cleveland residents who have few if any choices" (Krumholz et al., 1975; Krumholz, 1982). This goal made clear that Cleveland's poor and near-poor were to receive priority planning attention.

The Cleveland planners justified the choice of their goal with three arguments. First, they argued that a long-standing, historic moral commitment existed to seek more equity in the social, economic, and political relations among people. Second, building on the ideas of philosopher John Rawls (1971), they used reason as a means of justifying a more equitable society – the kind of society that free, equal, and rational people would establish to protect their own self-interests. Finally, they justified their goal by reality: making explicit the imbalances in income, education, health and other social and economic variables that existed in Cleveland between city and suburb, and white and black citizens (Cleveland City Planning Commission, 1975). Over the 10-year length of the equity planning experiment, and under three different mayors, the efforts of Cleveland's planners resulted in 'fair-share' low-income housing distribution plans for Cuyahoga County, progressive changes in Ohio's property law, improvements in public service delivery, enhancement of transit services for the transit-dependent population, the rescue of lakefront parklands, and many other improvements.

Another outstanding example of progressive politics and equity planning within city government was found in Chicago during the 1980s. Robert Mier, a planning professor who founded the Center for Urban Economic Development at the University of Illinois in Chicago, helped build a political coalition that in 1982 elected Harold Washington, Chicago's first black mayor. When elected, Washington took Mier and some of his associates into City Hall where they explicitly included "redistributive and social justice goals within the governments's policy, planning and implementation frameworks" (Giloth and Moe, 1999).

Mier and his fellow planners wrote the 'Chicago Economic Development Plan, 1984,' a model of equity planning. The plan proposed to use the full weight of the city's tax incentives, public financing, and infrastructure improvements to generate jobs for Chicago residents with emphasis on the unemployed. Specific hiring targets were set for minority and female employment; 60% of the city's purchasing was directed to Chicago businesses; 25% of that was to go to minority and women-owned firms.

The plan also sought to encourage a model of balanced, 'linked' growth between downtown Chicago and the city's neighborhoods. It offered public support to private developers interested in building projects in 'strong' market areas of the city, only if they would agree to contribute to a low-income housing trust fund or otherwise assist neighborhood-based community development corporations to build projects in 'weaker' areas.

Other American urban planners have adopted advocacy/equity approaches because they believe that planning along these lines holds the promise of better lives for the most troubled residents of their cities. In the 1980s and 1990s, equity planning cases were documented in cities such as Denver, Jersey City, San Diego, Berkeley, and Santa Monica (Krumholz and Clavel, 1994).

More recently, planners in some cities have been negotiating linkage deals and Community Benefits Agreements with developers, which offset subsidies or special rights granted by the city with special contributions by developers for low-income housing, job training, public transit, child care, or other

benefits for lower income people and neighborhoods (Wolf-Powers, Laura, 2010).

These cases make clear that there are often political and institutional barriers to equity planning practice, especially in a nation so strongly driven by market forces as the United States, and equity planners who question the status quo may face political reprisals. But obstacles to equity planning practice seem to lie primarily in the areas of the planner's personal confidence, motivation, and will.

A number of lessons seem clear. First, all forms of urban planning, especially advocacy/equity planning, prosper during periods of crisis, which bring forward the reform elements of the American state. It was during the Progressive Era that housing reform and urban planning were initiated. Later, when the Great Depression brought forth FDR's New Deal, planning was introduced for the first time into the federal government; sweeping regional projects like TVA got their start and the federal government involved itself in the provision of low-income housing. During the 1960s, the ferment around civil rights, antiwar protests, and the demolitions of urban renewal and the interstate highway program brought advocacy planners like Paul Davidoff, who combined commitment to social justice and democracy, to the fore.

Although the advocacy/equity planners often struggled against the more powerful currents of a strongly market-oriented society, they succeeded to an extent, and their work has been acknowledged and institutionalized. At the end of the twentieth century, American city planning was much more sensitive and collaborative than it had been earlier. Racial discrimination in housing and in mortgage lending has been prohibited by federal law, and citizens were encouraged to participate in the planning of programs that impacted their lives. Neighborhood-based development corporations have been successfully redeveloping parts of certain older neighborhoods, and some cities have been linking the benefits of downtown growth to their poor neighborhoods.

Also, since the global financial crisis of 2008, there is more interest in equity and advocacy in urban planning. Two cities, Minneapolis, Minnesota, and Portland, Oregon, have established formal offices on equity as part of regular government practice, and many more academics are writing about and studying progressive planning.

What remains troublesome, however, is the persistence of deep poverty in a growing number of urban neighborhoods, the continuance of patterns of racial segregation, the widening gap between rich and poor, the dismantling by conservative national administrations of the social safety net, the chronic competition among American cities that harms the vast majority of their citizens, and the growing spatial separation across metropolitan regions by race and class.

Given these challenges, a new generation of advocacy/equity planners is needed to help ease and resolve the most crucial of these social and physical issues, for what is at stake is nothing less than the future of urban life in America.

Advocacy in Anthropology

Abstract

Advocacy and public anthropology are discussed as particular variants of applied anthropology using the term in its broadest sense. Examples of highlighted advocacy and public anthropologists include David Maybury-Lewis of Cultural Survival, Luisa Maffi of Terra Lingua, Robert Borofsky of the Center for Public Anthropology, Paul Farmer of Partners in Health, and Barbara Rose Johnston of the Center for Political Ecology. The main criticisms of such advocacy and public anthropology are identified and discussed. Then some future prospects for these endeavors are suggested as well.

Advocacy Anthropology

Advocacy anthropology is the application of anthropological resources on behalf of the survival, welfare, rights, and self-determination of indigenous communities, ethnic minorities, and other groups. It is a particular variety of applied anthropology advancing the interests of a community, often as a practical plea on its behalf to one or more external agencies. The community is usually indigenes, peasants, an ethnic minority, or refugees, those who are among the most oppressed, exploited, and abused. Advocacy is often connected to human rights, a framework internationally accepted in principle although, not always followed in practice. (Human rights refer to the inalienable universal rights that every human being deserves to have protected and promoted such as access to adequate water, food, shelter, and health care as well as freedom of speech, assembly, and religion.) Advocacy encompasses a broad agenda for social and political activism by promoting cultural survival and identity, empowerment, self-determination, human rights, sustainable economy, and the quality of life of communities. Advocates reject the supposed neutrality of science and adopt a stance on some problem or issue to improve the situation of a community, ideally in close partnership with it. Thus, as an advocate the anthropologist is no longer just observer, recorder, and interpreter (basic research), nor consultant to an external agency (applied), but facilitator, interventionist, lobbyist, or activist for a community (advocacy) (Paine, 1985; Wright, 1988).

Advocacy usually operates from an idealist rather than realist position. Although these terms from John Bodley are problematic, the concepts are valid and useful. Realists accept cultural assimilation and even ethnocide (forced cultural change or extinction) as a natural and inevitable correlate of 'civilization,' 'progress,' and 'development,' a position sometimes linked with social Darwinism. Idealists reject this, viewing ethnocide as a political decision, usually by a government violating human rights. Realists dismiss idealists as romanticists who are trying to preserve indigenes as their private laboratories, zoos, or museums. However, idealists do not argue that culture is static and should be preserved as such; they argue only for self-determination by people to promote their cultural survival, identity, welfare, and rights. Self-determination is seen as the most basic of all human rights, whether referring to an individual, group, or society, and in principle it is limited only to the extent that it does not interfere with the rights of others. The pivotal moral and political issue is the right and power of the state to dominate indigenes or others and in some cases to implement ethnocide. Advocacy attempts to intervene in this power imbalance through demystifying the process, exposing injustices, and offering resistance (Bodley, 2008: 251–290).

Advocacy has a long history. For example, Bartolome de las Casas (1474–1566) – theologian, missionary, and something of a historian and anthropologist – participated in the first decades of European colonialism in the Americas. He chronicled injustice against indigenes and argued in their defense. By the mid-nineteenth century, the Anti-Slavery Society and the Aboriginal Protection Society emerged in England as humanitarian organizations campaigning for just policies toward indigenes and others. During this period, the early anthropological societies of London and Paris debated similar concerns. In the 1960s, organizations focused on advocacy developed, most notably Cultural Survival in Cambridge, Massachusetts; the International Work Group for Indigenous Affairs in Copenhagen; and the Minority Rights Group and Survival International in London (e.g., Corry, 2011). Each publishes newsletters, journals, and/or documents to expose human rights violations and analyzes issues; funds collaborative research with communities; and works to influence national and international governmental and nongovernmental agencies and the public, especially through lobbying, the media, and letter writing. Collaborative ethnography (a close partnership in the planning, implementation, analysis, reporting, and evaluation of ethnographic research with the host community), participatory action research, and needs assessment can be especially relevant for advocacy fieldwork.

Most of the history of advocacy as well as recent cases and issues can be found in the publications of the above advocacy organizations (e.g., *Cultural Survival Quarterly*) and in the journals *Current Anthropology* and *Human Organization*. More recently, special issues of the following periodicals are pertinent to advocacy anthropology: *American Anthropologist* (2006, v. 108, no. 1); *Anthropological Forum* (2012, v. 22, no. 1); *Anthropology in Action* (2003, v. 10, no. 2; 2009, v. 16, no. 2); *Current Anthropology* (2010, v. 51 Supplement 2); *Polar: Political and Legal Anthropology Review* (2005, v. 28, no. 2); *Practicing Anthropology* (2004, v. 26, no. 3; 2010, v. 32, no. 2); and *Urban Anthropology* (2003, v. 32, no. 2). Of historic interest as well is

the initiation of a public anthropology section in the *American Anthropologist* starting in September 2010.

At least two criticisms contributed to the development of advocacy: first, accusations of genocide and ethnocide of indigenes by colonials and neocolonials in 'frontiers' like the Amazon; and second, from outside and within anthropology criticisms of basic and applied research together with calls for increasing social relevance and responsibility, most recently termed engaged anthropology (an omnibus category for various initiatives in socially responsive and responsible anthropology).

In 1969, Vine Deloria, Jr., a Sioux lawyer and interdisciplinary scholar, launched a searing critique of anthropologists engaged in either pure research with natives as objects in their private zoo or applied work for the colonial government; only concerned with advancing their career for self-aggrandizement and money; and irresponsible and unresponsive to the needs and problems of Native Americans. He asserted that anthropologists should obtain informed permission from the host community for research, plan and implement it in close collaboration with them, and focus on their practical needs, problems, and concerns (Biolsi and Zimmerman, 1997).

In 1971, a historically important but neglected conference of mostly Latin American anthropologists developed the Declaration of Barbados which, among other things, criticized anthropology for its scientism, hypocrisy, opportunism, and apathy in the face of the oppression, exploitation, ethnocide, and genocide of indigenes by colonials and neocolonials. For some anthropologists this became a manifesto to join the struggles for liberation and self-determination of indigenes and ethnic minorities through advocacy (Dostal, 1972).

Cultural Survival was launched by David and Pia Maybury-Lewis along with Evon Z. Vogt, Jr. and Orlando Patterson on 2 March 1972. The office was housed in the Peabody Museum of Harvard University. They were responding to the increasing pressure on indigenous societies throughout the world, especially in the Amazon, from external agencies seeking land and resources since the 1960s, often with the rationalization of so-called economic development and progress bolstered by racist and ethnocentric stereotypes. As Prins and Graham (2008: 119) observe: "David recognized that the anthropologist's profession comes with moral obligations that may call for political action in solidarity with those who have become friends, neighbors, and, sometimes, even relatives during fieldwork."

Cultural Survival was established as a partnership working with indigenous communities on behalf of their survival, welfare, sovereignty, self-determination, and human rights. The founders felt that this was a way to genuinely reciprocate for the hospitality of indigenous communities in allowing and facilitating their field research. It was also a dire necessity as indigenes increasingly faced genocide, ethnocide, and ecocide.

David Maybury-Lewis (1929–2007) was a public as well as an advocacy anthropologist. In articles in the *New York Times* and various other newspapers and magazines, he argued in favor of idealism and against realism, as previously distinguished here. His bottom line was that ethnocide through forced acculturation and assimilation is not inevitable, but a matter of political choices. Thus, he advocated an appreciation and tolerance for cultural diversity in a multiethnic society. Furthermore, he hosted the 10 one-hour documentary film series on the British Broadcasting Corporation and in the United States on the Public Broadcasting Service called 'Millennium: Tribal Wisdom and the Modern World' and wrote a companion book by the same title. The film is the product of 10 years of work in 15 countries. It employs first-person narratives with indigenous and Western persons to describe the nature, meaning, and significance of cultural diversity and the underlying universal themes. Thereby it exposed the massive audience of television to new ways of thinking about living and the environment. By now the film has been viewed by more than 50 million people in a dozen countries (Prins and Graham, 2008: 120). The initial showing coincided with the Columbian Quincentenary.

It should be noted that as a pioneering Amazonian ethnographer and a professor of anthropology at Harvard University, Maybury-Lewis was internationally recognized as a distinguished academic scholar and scientist as well as esteemed for his deep and tireless devotion to advocacy. Throughout his career, basic and applied research were mutually reinforcing (e.g., Maybury-Lewis, 2002).

Terralingua is an advocacy organization similar to Cultural Survival, except it is focused on the languages of the world within the framework of the concept of biocultural diversity, encompassing biological, cultural, and linguistic diversity. The organization advocates the study, documentation, and preservation of the linguistic diversity of the world's 6867 ethnolinguistic groups. Luisa Maffi, a linguist, anthropologist, and ethnobiologist, is cofounder and director of Terralingua. The organization was established in 1996 by several dedicated individuals from various backgrounds who had a common concern for the vital importance of biocultural diversity and its maintenance. In association with Terra Lingua, Maffi has published several seminal books in this arena. The organization publishes an e-magazine called *Langscape* (Terralingua, 2012).

Terralingua's work overlaps with public as well as advocacy anthropology. Their website identifies these fundamental beliefs: the diversity of life on earth has biological, cultural, and linguistic components (biocultural diversity); these coevolved in an interdependent and mutually reinforcing manner; there is a rapid, converging crisis of extinction of biocultural diversity and it is imperative to stop this crisis for the survival of all life on the planet; healthy environments, resilient cultures, and vibrant languages are a matter of social justice and basic rights for human societies, including indigenous and local communities; the challenge is to protect, maintain, and restore the earth's biocultural diversity. These beliefs guide the work of Terralingua through innovative initiatives in basic and policy-related research, activism on the ground, and education (Maffi, 2005; Terralingua, 2012).

The San and other peoples of the Kalahari region of southern Africa have been studied extensively by anthropologists from various countries for well over a century. Some of these anthropologists have been particularly conscientious in reciprocating in meaningful ways to the communities who hosted their field research. Most notable is the Kalahari Peoples Fund building on the ethnographic work of Richard B. Lee and others initiated by the Kalahari Research Group of Harvard University. Since 1973, the Kalahari Peoples Fund

has responded to various requests to raise money and to assist with advice and technical matters as major cultural changes spread into the area. Professional anthropologists have volunteered to serve as liaisons with the government for communities advocating in many ways on their behalf such as for health care, natural resource rights, legal matters, education, and emergency situations. The organization also provides information and research on Kalahari peoples for lawyers, students, volunteers, and tourists. Members make presentations in numerous national and international forums to inform academics and the public about the current situation of the Kalahari peoples. Many anthropologists working in the area consider it to be morally impossible not to be engaged on behalf of the people they work with (Biesele, 2003; Lee and Biesele, 2002).

Public Anthropology

During the last decade there has been a marked growth of interest in what may be viewed as a variant of advocacy anthropology; namely, public anthropology. Public anthropology is the application of anthropology for the general public focused on specific public concerns. However, in public anthropology, instead of a local community being the focus, society usually is, especially the anthropologist's own society. The purpose is to apply anthropological knowledge, theories, and methods to better inform the public about contemporary questions, problems, issues, and controversies. Public anthropology is not new, although the term and trend are. Franz Boas (1858–1942), and many of his students such as Margaret Mead (1901–1978), Ruth Benedict (1887–1948), and Ashley Montagu (1905–1999), were public intellectuals who addressed public concerns as engaged scholar activists (Low and Merry, 2010).

In the last two decades, however, Robert Borofsky has been the most vocal proponent advocating public anthropology to counter a discipline that seemed to be increasingly insular and esoteric to a general public and often consumed by internal bickering instead of critical sociopolitical issues. He has pursued advancing public anthropology through organizing sessions and speakers at the annual convention of the American Anthropological Association (AAA), editing more than two dozen books in the California Series in Public Anthropology for the University of California Press at Berkeley since 2001, his website Public Anthropology (2012), and his own publications. For Borofsky, the *sine qua non* of public anthropology is for a far greater percentage of anthropologists to address public problems for the public, thereby fostering transparency and accountability beyond academia. Borofsky pursues a professional ethical stance beyond the fundamental principle of do no harm. His view is that in addition, do some good.

In his exploration of anthropology as a cultural construction which he calls the anthropology of anthropology, Borofsky is challenging the status quo of the establishment, especially the AAA, and in particular, the structures that subvert public engagement. He encourages student activism through the Community Action project. The California Series in Public Anthropology offers positive role models for change. His Public Outreach Assessment is one way that he seeks to draw on political forces beyond academia by ranking doctoral programs in anthropology on the basis of their public outreach. (Information about these and other advocacy initiatives by Borofsky are available on his website Public Anthropology.)

The remarkable work of Paul Farmer for nearly three decades illustrates the overlap in the various manifestations of applied anthropology in general as previously mentioned, and also the importance of applied anthropology being anchored in basic research. (In general, applied anthropology is the use of anthropology to solve practical problems.) A PhD medical anthropologist who is a practicing MD as well, Farmer developed a sophisticated social, clinical, and epidemiological analysis of health and social inequalities with a focus on tuberculosis and HIV/AIDS. Among other countries, he has pursued field research in the squatter settlements of Haiti. Farmer was appointed UN Deputy Special Envoy to Haiti to assist Special Envoy Bill Clinton in improving economic and social conditions.

As a public health advocate for the poorest of the poor, Farmer is the Founding Director of Partners in Health (PIH), an international social justice and health nongovernmental organization. PIH provides free direct health care to the poor, pressures pharmaceutical companies for medicines, and lobbies policy makers. It pursues basic research and advocacy on behalf of the poor in the development of community-based comprehensive primary health care. By now, the organization has expanded beyond its original localities in Haiti to encompass more than 11 000 employees in 49 health centers and hospitals in 11 countries (Partners in Health, 2012).

Grounded in his ethnographic fieldwork on the front lines of poor communities, Farmer's extensive publications focus mainly on the relationship between health and human rights through scrutinizing the role of social inequities in the distribution and outcome of infectious diseases. His work critically challenges conventional thinking about human rights revealing how social, economic, and political injustices influence the suffering and illness of the impoverished and powerless. He argues that 'business as usual' in any venue simply manages inequality instead of confronting structural violence (Farmer, 2002). On 28 November 2011, *Foreign Policy* magazine listed him among the top global thinkers. Farmer is also the subject of a biography by Kidder (2003), which reached the bestseller list of the *New York Times*.

Another outstanding leader in advocacy and public anthropology is Barbara Rose Johnston, Senior Researcher at the Center for Political Ecology (2012). Primarily known as an environmental anthropologist, but overlapping with medical anthropology, Johnston has focused much of her research and publications on the interface between environment and human rights, and in particular, human environmental rights. Many inalienable universal human rights depend on a healthy environment. Environmental problems are not experienced equally; instead inequities render some persons more vulnerable than others.

Johnston's recent research focuses on the biomedical, psychosocial, cultural, and environmental impacts of the US nuclear weapons testing program, encompassing the history and consequences of its classified human radiation experimentation program. Since 1999, Johnston has served as a scientific advisor and expert witness for the Marshall Islands

Nuclear Claims Tribunal. She has pursued recognition and implementation of the right to a healthy environment, environmental equity, and the right to reparation and remedy. She played a very significant role as a researcher and expert witness in the award of over a billion dollars by the Nuclear Claims Tribunal to the victims on Rongelap in the Marshall Islands.

Johnston has published several books as editor or co-author, and was series editor of the eight volumes of regional surveys aimed at high school and college students titled *Endangered Peoples: Struggles to Survive and Thrive in a Globalized World*. She has published in public media such as *Counterpunch*. Her books are readily accessible to the general public as well as solidly grounded in scientific and academic scholarship. Contributing authors to her edited books are among the more prominent individuals in advocacy, public, and engaged anthropology.

Furthermore, Johnston has discussed the complexities, difficulties, and the personal and professional risks of work in advocacy and public anthropology. In particular, the 'anthropology of trouble' (Rappaport, 1988) can bring personal trouble to the anthropologist. It requires serious commitment, courage, persistence, and endurance as well as scientific and scholarly expertise and skill. It may also prevent or jeopardize academic jobs, given the usual criteria for employment, promotion, and tenure commonly focused exclusively on basic research, establishment grants, and publications in standard scientific journals (Low and Merry, 2010). (See Johnston, 2010, for a reflective overview of her work and citations for her publications.)

Another term, engaged anthropology, includes advocacy and public anthropology, but is much broader and more diverse. Engaged anthropology is an omnibus rubric for a broad variety of initiatives pushing for a more socially responsive and responsible anthropology. It includes sharing, support, and collaboration with host communities for research, teaching and public education, social critique, advocacy, and activism. It has attracted increasing attention for more than a decade. Growing engagement is transforming the discipline's approach and relationship with those studied in fieldwork and with the scholarly community as well as the general public (Low and Merry, 2010). There are diverse motivations for a more engaged anthropology, but a major one is simply that the discipline must go public or perish (e.g., Peacock, 1997). However, in their superb overview of engaged anthropology, Low and Merry (2010: S204) identify another motivation: "Personally, the reason we are interested in engaged anthropology is that we are committed to an anthropological practice that respects the dignity and rights of all humans and has a beneficent effect on the promotion of social justice."

Finally, although too complicated to consider in detail here, another arena for the various manifestations of applied anthropology should be at least mentioned; that is, global climate change, the newest agency of ethnocide and ecocide. Its reality can no longer be questioned by any informed person who is honest, given the consensus of hundreds of scientists throughout the world as represented in the Intergovernmental Panel on Climate Change. The only questions are how bad is it going to get, and how will humans adapt? The first book in anthropology to confront this challenge was edited by Susan A. Crate and Mark Nutall as recently as 2009. It is a comprehensive assessment of the anthropology of global climate change with emphasis on witnessing the lived-reality of local impacts on place-based indigenous and other rural communities thereby putting a human face on climate change. It is important to point out that global climate change has a multiplier effect; it exacerbates other problems as well. The authors affirm the veracity and utility of local environmental knowledge and concerns. Furthermore, the authors advocate action with creative suggestions on engaging the public and policy to promote economic and social justice and rights for the vulnerable communities impacted from the material to the spiritual aspects of their unique lifeways from a distance by the poisoning of the atmosphere by more powerful industrial countries obsessed with materialism and consumerism. Many of the anthropologists are convinced that such activism is morally and ethically imperative because they are citizens of the countries primarily responsible for causing the problem (also see Crate, 2011).

Criticisms

There have been criticisms of advocacy and public anthropology from within the profession, mainly for supposedly abandoning scientific objectivity and reducing or abandoning anthropology to some form of social work or political activism. For instance, Peter Elsass (1992) asserts that anthropology rests on criteria of science, objectivity through neutrality, and scholarship for the creation of knowledge; and advocacy on morality and the use of knowledge. He opines that anthropologists are ill equipped to deal with matters such as the politics of state penetration into indigenous areas. He worries that advocacy may make things worse in the community and jeopardize the credibility and prestige of basic research. Elsass believes that fieldwork, moral commitment, a sense of justice, political observation, and anger on behalf of the community are all part of the decision to advocate, but that anthropology as science and scholarship does not lead to advocacy. Carolyn Flueher-Lobban (2006), the foremost student of professional ethics in anthropology, has argued that advocacy is not a professional ethical responsibility, although it may be a personal moral responsibility and choice.

Rebuttal

The response to critics such as Elsass has focused on four things. First, in a general sense most if not all anthropologists are advocates and public intellectuals in some degree and manner. At least since Franz Boas, teaching anthropology advocates the value of the profession, cultural diversity, and cultural relativism; research publications advocate certain arguments, theories, and methods; and both teaching and research may challenge racism and ethnocentrism in favor of valuing equality, justice, and rights.

Second, no science or scientist is totally apolitical and amoral. In particular, when ethnocide, genocide, or other human rights violations occur, it is simply unconscionable and unprofessional for a knowledgeable anthropologist not to act, especially if directly involved with the society or community.

This is implicit in the code of ethics of professional organizations like the AAA, numerous resolutions at its annual meetings over many decades, and the mission and activities of its Committee on Ethics and especially the Committee for Human Rights.

Anthropologists are unavoidably immersed in webs of political relationships (Low and Merry, 2010). Alcida Rita Ramos (1999) argues that doing anthropology anywhere in the world is inevitably a political act, whether or not the anthropologist is aware of or recognizes that fact to any degree, and whether or not the anthropologist likes it. David A. Cleveland (1994: 9) has framed this issue particularly well: "Choosing between science and advocacy is not valid, because it does not serve the goals of either science or advocacy…. We are in fact always advocates—by not making active choices, we are passive advocates for the status quo…. The challenge is to keep up a dialogue between science and advocacy, keeping the two as distinct as possible without separating them completely."

Third, many communities believe that either the anthropologist is part of the solution, or part of the problem. Increasingly, communities are excluding anthropologists, unless they demonstrate social responsibility and relevance. Indeed, if anthropology is not of some genuine relevance to the communities from which research is derived, then some would suspect its credibility as well as utility. How could data collected in a given community be irrelevant to it? Even when a community can readily speak and fight for itself, it usually helps to have an outsider with some special knowledge, resources, and access to speak as well. However, a major dilemma for the anthropologist is dealing with messy inter- and intracommunity factions and conflicts.

Fourth, while avoiding paternalism, many anthropologists are involved in advocacy and public anthropology because they are sincerely concerned with applying knowledge on behalf of the communities who are indispensable for their research, as an expression of genuine reciprocity, and to avoid dehumanizing their hosts and themselves. An outstanding example of such advocacy is the collaboration of Bruce Albert and Gale Goodwin Gomez (1997) in researching and publishing a bilingual ethnomedical guide in Portuguese and Yanomami to facilitate the work of health care workers. Likewise, individuals who commit to the discipline of anthropology as their career and lifestyle, and as conscientious citizens, are often moved to demonstrate its relevance beyond academia to society as a whole through public anthropology (e.g., Johnston, 2010).

Conclusions

Advocacy and public anthropology are manifestations of applied anthropology along with practicing, action, collaborative, and engaged anthropology. There is much overlap among these often ambiguous and/or politicized approaches, the difference being mainly in their focus and clientele. They have all grown exponentially since the 1960s, and especially during the 2000s. It appears most likely that the anthropology of the twenty-first century is going to be quite different in many respects from that of the previous centuries, but grounded in deep historical roots even as it challenges prevailing orthodoxies.

In the future, advocacy needs to more systematically and explicitly develop its foundations and operations in terms of its history, philosophy, theory, methods, ethics, practice, and politics. Also, it should be recognized that there are many ways to contribute to advocacy, such as teaching, even for those critical of its complexities, difficulties, and risks. To be effective, advocacy and public anthropology must be grounded solidly in basic research, but they can also feed into further development of theory and method.

Advocacy, public, and other varieties of applied anthropology are most likely to increase in the twenty-first century because of at least three factors: first, growing population and economic pressures on land and resources with ensuing competition, conflicts, violence, and rights violations; second, increasing encroachment of the state, military, business, industry, and other external forces on indigenous and other communities; and third, insistence by local communities who host field research that anthropologists become more responsible and thereby responsive. Most 'frontier' or 'underdeveloped' zones in the world are in the traditional territory of indigenous societies. There are 350 million indigenous persons in the world, and although they comprise only 5% of the world population, they inhabit 20% of its land mass in 70 countries (Maybury-Lewis, 2002: 7–8). The pressure on indigenous peoples is growing and many conscientious anthropologists are responding accordingly. Advocacy and public anthropology are likely to continue developing well into the future as a significant component of the conscience of anthropology, or at least of some anthropologists.

Ultimately, advocacy anthropology and public anthropology are a matter of personal morality and professional ethics as well as science and scholarship, and, of course, also politics. As Pat Caplan (2003: 3) observes: "Yet the ethics of anthropology is clearly not just about obeying a set of guidelines; it actually goes to the heart of the discipline; the premises on which its practitioners operate, its epistemology, theory and praxis. In other words, *what* is anthropology for? *Who* is it for?"

Aesthetic Education

Tracie E Costantino, Rhode Island School of Design, Providence, RI, USA

This article is a revision of the previous edition article by R.A. Smith, volume 1, pp. 206–210, © 2001, Elsevier Ltd.

Abstract

While acknowledging the foundational role of the arts in human development, this article will focus on twenty-first century conceptions and manifestations of aesthetic education. This discussion will highlight key theorists John Dewey and Maxine Greene, focusing on their scholarship from the twentieth century that continues to inform aesthetic education and powerfully articulates the ongoing significance of aesthetic education for human civilization. The main portion of this article will review the status of aesthetic education in the early twenty-first century amid an educational culture of accountability, standardization, and global economic competition, with a snapshot focus on the United States.

Introduction

Regardless of the waxing and waning of the presence of the visual and performing arts in formal education throughout the history of Western civilization, the importance of the arts in the development of human culture is undisputed. Ellen Dissanayake (1995) has attributed an ethological function to the arts, asserting that artistic behavior is a fundamentally human proclivity. Cognitive scientist Merlin Donald (2006) has argued that artistic behavior was part of a distributed cognitive system that influenced the evolutionary development of the modern *Homo sapien* brain. This distributed cognitive system – culture – continues to shape human development. With such profound influence on human evolution, the study of the arts is certainly justified. Aesthetic education may, following this argument, be defined as engagement with manifestations of human artistic expression throughout history for mutual cultural education, both local and global. Encountering works of art from one's own society, and the societies of others, educates individuals in the mores and values of diverse cultures, cultivating a tolerance for pluralism that has often aligned aesthetic education with ethics, democracy, and moral education.

While acknowledging the foundational role of the arts in human development, this article will focus on twenty-first century conceptions and manifestations of aesthetic education. This discussion will highlight key theorists John Dewey and Maxine Greene, focusing on their scholarship from the twentieth century that continues to inform aesthetic education and powerfully articulates the ongoing significance of aesthetic education for human civilization. The main portion of this article will review the status of aesthetic education in the early twenty-first century amid an educational culture of accountability, standardization, and global economic competition, with a snapshot focus on the United States. The focus on twenty-first century perspectives on aesthetic education is deliberate in order to underscore the ongoing relevance of aesthetic education, which has been critiqued as an unnecessary leftover from modernism (Tavin, 2007), to contemporary pragmatist, postmodern, poststructuralist, and social reconstructionist aims for education (see chapter by Costantino and chapter by jagodzinsky in Costantino and White, 2010).

A Brief History of Aesthetic Education

While an extensive documentation of the history of aesthetic education is beyond the scope of this article (see White, 2009), it is pertinent to begin with a brief history of the development of aesthetic education since the Enlightenment. The advent of modern aesthetic education may be considered as early as the eighteenth century when the German philosopher Alexander Baumgarten (1714–62) established aesthetics as a field of study within philosophy. Baumgarten's emphasis on aesthetics as a study of sense-perception initiated inquiry into how aesthetic perception may be developed through experience and education. Immanuel Kant (1724–1804) built on the work of Baumgarten to become the leading philosopher of aesthetics into the twentieth century, seeking to establish aesthetics in the realm of reason with his pivotal treatise *The Critique of Judgment*. Indeed, White acknowledges that "much of the contemporary controversy regarding aesthetics emerges from Kant's writings" (2009: p. 27).

Aesthetic education as a component of moral education gained prominence through the seminal work of Friedrich Schiller (1759–1805) *On the Aesthetic Education of Man* and the concept of *bildung* in German philosophy of the nineteenth century. In the first half of the twentieth century the influence of *bildung* continued in the aesthetic theories of hermeneutic philosophers Martin Heidegger (1889–1976) and Hans-Georg Gadamer (1900–2002). In the United States in the early twentieth century aesthetic education as moral education was evident in the picture study movement entailing the distribution of fine art prints to schools for the cultural edification of students. As Efland (1990) explained, "American art educators of that period were anxious to connect art study with the acquisition of American virtues, especially for the children of immigrants" (p. 146).

While the formalization of education through compulsory schooling in the nineteenth century influenced the opportunity for aesthetic education for different groups depending on local resources and priorities, since the advent of the standards and

accountability movement in the United States, there is documented discrepancy in the availability of aesthetic education for different socioeconomic and racial/ethnic groups, to be reviewed below.

What Is Aesthetic Education?

Aesthetic education is the cultivation of aesthetic understanding and the imagination through active engagement with the visual and performing arts. By engaging with works of art from diverse genres and cultures, students develop the ability to interpret and make meaning from an increasing variety of modes of expression, and through arts practice are able to communicate through multiple forms of representation. Elliot Eisner wrote in *Cognition and Curriculum, Reconsidered* (1994) of the importance of providing learners with different forms of representation through which they may communicate meaning. According to Eisner, "forms of representation are the devices that humans use to make public conceptions that are privately held …This public status might take the form of words, pictures, music, mathematics, dance, and the like" (p. 39). Eisner (1994, 2002) wrote extensively on the significance of this multimodal flexibility for cognitive development as students develop productive habits of mind such as attention to relationships, tolerance of ambiguity, resistance to premature closure, and feelings of self-efficacy to name a few. Eisner's ideas about the cognitive potential of arts education was significantly informed by John Dewey's writings on qualitative thought and his aesthetic theory of art as experience.

John Dewey: Training Aesthetic Perception for Democracy

John Dewey (1859–1952), American pragmatist philosopher and educator, sought to return the arts to everyday life in his influential work of aesthetic philosophy *Art as Experience* (1934). Critical of the removal of the arts from communal life into the rarefied "economic cosmopolitanism" (1934: p. 7) of museums and galleries, Dewey situated aesthetic experience as part of the continuity of the process of life. In his theory of art *as* experience, he gave perception a primary role in aesthetic experience. He explained the role of perception as the recognition of relationships. Simple recognition, however, is only the beginning of perception – it is the identification of elements without identifying how they are related. Perception is the interpretation of how various parts of an experience relate to form a unified whole. Discerning this relationship constitutes the meaning-making process: "The action and its consequence must be joined in perception. This relationship is what gives meaning; to grasp it is the objective of all intelligence" (1934: p. 44). The perception of relationships is what gives an experience its satisfying emotional quality. It is what makes an experience aesthetic. Dewey emphasized that the experience of art requires perception in order for it to constitute an aesthetic experience. In other words, Dewey declared that "to be truly artistic, a work must also be esthetic – that is, framed for enjoyed receptive perception" (p. 48). Dewey defined artistic as the relationship between making and perceiving: "The act of producing that is directed by intent to produce something that is enjoyed in the immediate experience of perceiving has qualities that a spontaneous or uncontrolled activity does not have" (p. 48). In essence, art requires the application of intelligence as opposed to random, disassociated thoughts or feelings; it derives from qualitative thought.

Qualitative thought, Dewey explained, is an associative process in which significant relationships are intuitively grasped in an experience "… the immediate existence of quality, and of dominant and pervasive quality, is the background, the point of departure, and the regulative principle of all thinking" (1930/1984: p. 261). Dewey described artistic thinking as an exemplar of qualitative thought. "The logic of artistic construction and esthetic appreciation is peculiarly significant because they exemplify in accentuated and purified form the control of selection of detail and of mode of relation, or integration, by a qualitative whole" (p. 251). Dewey considered the thinking required for artistic creation to be "one of the most exacting modes of thought" (1934: p. 45). Likewise, the act of perceiving a work of art requires the same kind of intelligence. It is a creative act, or an act of "reconstructive doing" (1934: p. 53), that requires cultivation. For Dewey, the appropriate end of training aesthetic perception is a richer everyday life. Dewey's dismantling of the fine versus applied art distinction in *Art as Experience* brings art into the realm of everyday life, thereby democratizing aesthetic experience as something attainable for all. Dewey's (1916) emphasis on education as a democratizing force, and his location of the arts in the midst of civilization was a critical influence for the philosophy of aesthetic education developed by Maxine Greene.

Maxine Greene: Releasing the Social Imagination

Maxine Greene (1917–2014), Professor Emeritus at Teachers College Columbia University and Philosopher in Residence at the Lincoln Center Institute, has defined aesthetic education as "deliberate efforts to foster increasingly informed and involved encounters with art" (1995: p. 138). Maxine Greene (1988, 1995) has written extensively on how experiences in and through the arts can stimulate the imagination to provide openings for thinking of what might be. Greene has explained, "One of the reasons I have come to concentrate on imagination as a means through which we can assemble a coherent world is that imagination is what, above all, makes empathy possible" (1995: p. 3). Her idea of the social imagination, "the capacity to invent visions of what should be and what might be in our deficient society" (p. 5) focuses on using the arts as entry points for dialogue that cultivates a pluralism that is the foundation of democratic communities. Through the empathic relationships constructed via aesthetic experience, schools and classrooms can become communities in which students may imagine the open possibilities of their lives, and both teachers and students may embrace the diverse perspectives and experiences of those they may consider 'other.'

While Greene has emphasized the transformative quality of aesthetic experience in dialogue with works of art (the visual, literary, and performing arts), encouraging teachers to share art with their students as a means of releasing their imaginations of what might be, she also addresses the potential of art making for cultivating the social imagination, for creating an 'in-between' space where community may be built. "In

thinking of community, we need to emphasize the process words: making, creating, weaving, saying, and the like" (1995: p. 39). Indeed, Greene calls for a merging of the pedagogies of art education and aesthetic education so that students and teachers are engaged in both the making and seeing of possibility:

> I would like to see one pedagogy feeding into the other: the pedagogy that empowers students to create informing the pedagogy that empowers them to attend (and, perhaps, to appreciate) and vice versa. I would like to see both pedagogies carried on with a sense of both learner and teacher as seeker and questioner…reflective about his or her choosing process, turning toward the clearing that might (or might not) lie ahead (p. 138).

Greene's work continues to inform and guide contemporary practices in aesthetic education. Stories of encounters with Greene's aesthetic education pedagogy are memorialized in *Dear Maxine* (Lake, 2010), a series of letters to Maxine Greene from those who have been inspired by her work.

Contemporary Practices in Aesthetic Education

Building on the ideas of Maxine Greene, contemporary social reconstructionist curriculum theorists, such as Patrick Slattery (2013), utilize artistic forms in their research, theorizing, and teaching praxis focused on issues of social justice to create 'sudden shocks' of awareness (Greene, 1995: p. 36). Others build on the relational aesthetics of Nicolas Bourriaud (2002) to explore how contemporary art practice may inform K-12 art education (Irwin and O'Donoghue, 2012; O'Donoghue, 2009). Boyd White (2009) has developed a research model, the aesthetigram, informed by art criticism to map participants' interpretive process during aesthetic experience. Aesthetics has also influenced the conduct of qualitative research in education. Drawing on the I–Thou relationship described in the philosophy of Martin Buber (1970 (1923)) and the intimacy of aesthetic experience articulated by John Armstrong (2000), Liora Bresler (2009; and chapter in White and Costantino, 2013) has explored the potential of aesthetic experience to cultivate empathy in her conceptualization of the researcher–participant relationship in qualitative research. While the examples of contemporary practice just given reflect the activity of scholars working in aesthetic and arts education, the aim of aesthetic education is typically geared toward elementary and secondary education.

Status of Aesthetic Education

While most developed nations include the arts and creativity in their national curriculum, or curricular goals in the absence of a national curriculum, the status of the arts and creativity as an educational priority varies. In 21 countries surveyed by the International Review of Curriculum and Assessment Frameworks Archive, most countries emphasize arts practice, especially when the arts subjects of music and visual art are taught as separate disciplines, rather than social/cultural outcomes of arts learning as might be emphasized in aesthetic education. However, when arts education is conceptualized as a general arts course, there is more emphasis on social/cultural outcomes (INCA, 2004) (as was articulated in the aesthetic education philosophies of Maxine Greene and John Dewey).

Singapore's national curriculum reflects the partnership between arts appreciation and arts practice envisioned by Maxine Greene. For example, the two main aims for the curriculum in visual art education at the primary and secondary level are for students to develop visual literacy and to appreciate art. Art practice is encompassed within the aim of visual literacy as students make meaning of what they observe in their environment as well as communicate meaning through art making. The aim of appreciating art is not exclusively for transmitting cultural values and cultural heritage, but for understanding the value of art in students' lives and as a means of developing self-worth. The approach is similar for music education. The conceptualization of arts education in Singapore as reflective of aesthetic education is also made evident in the administration of these programs under the category of aesthetics, health, and moral education in Singapore's Ministry of Education (Ministry of Education, Singapore, n.d.).

Similarly, in the Republic of South Africa, the arts fall under the curriculum category of life skills at the primary and early secondary levels, with the inclusion of craft, however in the upper secondary level the focus is on the relationship between art and culture. However, cultural literacy and creativity are not included as national education aims in the Republic of South Africa (INCA, 2013).

As an example of the arts and creativity as a priority in national curriculum aims, in 2001 the United Kingdom established the Creative Partnerships program to address concerns over a narrowing focus on mathematics and literacy in the National Curriculum. The program created long-term partnerships between schools and creative professionals from the arts, science, and industry. These programs had positive associations with student attendance rates at elementary schools and academic attainment especially at secondary schools (Sharp and Cooper, 2012); despite this the UK government stopped funding the program in 2010 as a result of the economic crisis affecting Europe and the United States. Alternatively, in a report published in 2010 by the Ministry of Education and Culture in Finland, the arts are tied to the creative economy and therefore viewed as a contributor to the growth of Finland's national economy. Finland is highlighted here due to current international focus on the effectiveness of Finland's educational system as reflected in Finnish students' consistent high-level achievement on the Programme for International Student Assessment.

In the United States, the report from the President's Committee on the Arts and the Humanities, *Re-Investing in Arts Education: Winning America's Future Through Creative Schools* (2011), puts creativity in the spotlight with arts education as a primary vehicle for American economic success. This goal is stated clearly in the executive summary:

> In order to effectively compete in the global economy, business leaders are increasingly looking for employees who are creative, collaborative and innovative thinkers. A greater investment in the arts is an effective way to equip today's students with the skills they will need to succeed in the jobs of tomorrow (p. 1).

The report advocates for increased arts integrated curriculum in schools and a greater role for teaching-artists among its recommendations (an oft utilized model in aesthetic education). Whether this report will have an actual impact on federal and state education policy remains to be seen within a climate of Race to The Top that focuses on STEM disciplines (science, technology, engineering, and mathematics) and ongoing standardization through the common core movement, especially as the current provisions for arts education in the United States demonstrate significant inequities across socioeconomic status.

Snapshot: Status of Aesthetic Education in the United States

A significant portion of this research was previously synthesized in the report by T. Costantino, "Educational Equity Challenged: Evidence of Decreased Provisions for Arts Education Since the Enactment of No Child Left Behind" printed in the following conference proceedings: E. DeBray-Pelot (Ed.) (November 2009) *Critical Perspectives on Federally Driven Assessment Policy*, (pp. 63–82). Athens, GA: Education and Evaluation Policy Center, University of Georgia.

In the United States, arts advocates had to lobby forcefully to have the arts included in the Goals 2000 legislation of 1994. One of the main goals of this legislation was the development of a challenging curriculum based on rigorous content standards that states were encouraged to develop. It was only at the eleventh hour that the fine arts were considered a part of the core curriculum in this legislation. Again in 2001, when the No Child Left Behind (NCLB) legislation was enacted, arts advocates had to lobby for the fine arts to remain part of the core curriculum for which content standards were now mandated. When NCLB was signed into law in the United States, there was considerable concern that the accountability emphasis on reading and math would result in a detrimental narrowing of the elementary school curriculum. In a review of research on the influence of this law on the implementation of curriculum in American schools, two trends emerged. The first trend is a narrowing of the curriculum showing decreased instructional time for art and music, and even greater decreases in instructional time for social studies, resulting in minimal cultural education for students. The second significant trend is that these instructional time decreases were more pronounced in schools serving a majority of low-income and minority students and schools designated as failing according to NCLB guidelines. The nonprofit organization, Center for Education Policy (CEP), has published a series of reports tracking NCLB, but theirs is not the only research to demonstrate these trends, including the nonprofit sector (CEP, 2007, 2008; von Zastrow, 2004), the federal government (Government Accountability Office and National Assessment of Educational Progress), and from the arts education arena (Mishook and Kornhaber, 2006). Building on this trend, correlational research has also been conducted examining the relationship between arts engagement and positive social and academic outcomes for adolescents and young adults of low socioeconomic status (Catterall et al., 2012). Beyond the K-12 arena, a survey on arts participation in the United States reinforces the implications of this trend for arts participation (Rabkin and Hedberg, 2011).

Reduction in Instructional Time

In a nationally representative survey of 349 responding school districts conducted in 2006–07, a report by CEP (2008) showed that 16% of responding districts cut art and music by 57 min per week, which represented a 35% decrease in weekly instructional time. However, more districts reduced time for social studies (36%) and for a greater duration at 76 min per week. For those districts that both increased time for math and English language arts, and decreased time for other subjects, these districts cut weekly instructional time for the arts by 35% (from 154 to 100 min).

The Council for Basic Education (CBE) is a nonprofit organization concerned with the status of a liberal arts education for K-12 students in the United States. The CBE surveyed a stratified random sample (urban, suburban, rural, elementary, and secondary) of public school principals in Illinois, Maryland, New Mexico, and New York about the status of liberal arts subjects in their schools' curriculum (von Zastrow, 2004). The survey had a 32% return rate (956 principals). In addition to asking about existing changes in instructional time since 2000, the CBE survey asked principals about their expectations for changes in the next 2 years.

Unfortunately, the report does not specify results according to the elementary or secondary level, so findings are aggregated for these two groups, unless there is a notable difference between the two groups. For all data, the report does present findings according to low or high minority schools, as this reflects an alarming trend that the CBE report identified and intends to highlight. Specifically, the CBE study found that 25% of all responding principals reported decreases in instructional time for the arts, with 36% of high-minority school principals reporting decreases. A large percentage of high-minority school principals anticipated future decreases (42%). For one-third of the high-minority schools reporting decreases, the principals reported large decreases and also expected future decreases to be large. The report summarized, "we found that the greatest erosion of the curriculum is occurring in schools with high minority populations – the very populations whose access to such a curriculum has been historically most limited" (p. 7).

A study by the United States Government Accountability Office (2009) reported similar findings to that of the CEP and CBE, although to a lesser degree. At the request of Congress, the Government Accountability Office (GAO) conducted a study of whether student access to arts education had changed since the enactment of NCLB and if so, how. Congress also wanted to learn about current knowledge of the impact of arts education on student learning outcomes. In other words, how might changes in provisions for arts education in the curriculum affect student learning? Congress also wanted to know what school district officials were doing to provide arts education since NCLB and their challenges in this regard (pp. 1–2). The GAO used data collected by the Department of Education's National Longitudinal Study of NCLB, which surveyed elementary school teachers about changes in instructional time for all subjects between school years 2004–05 and 2006–07. It also surveyed arts officials in state education agencies in 49 states and the District of Columbia and conducted interviews with school district officials and site visits to individual schools in Illinois,

Massachusetts, Florida, and New York. These states were chosen for their large numbers of schools not meeting Annual Yearly Progress and for a diversity of school districts with varying household income levels and rural and urban populations.

The GAO study found that the majority of elementary school teachers surveyed (90%) indicated that instructional time for the arts had not changed from 2004–05 to 2006–07. The teachers came from a range of school demographic characteristics. However, 7% reported a decrease, and there was a statistically significant difference in school characteristics in this group compared to the majority response of no change. "Specifically, teachers at schools identified as needing improvement and those with higher percentages of minority students were more likely to report a reduction in time spent on the arts" (p. 3). Also, the decrease in instructional time for the arts was greater at schools with high percentages of low income or minority students, a 49-min decrease per week compared to a decrease of 31 min weekly. Although the 7% finding is almost half as much as the 16% of districts reporting decreases in instructional time for the arts found by the CEP, the GAO survey studies just a two-year time span, which occurred a few years after the enactment of NCLB. Indeed, the decreased instructional time may have occurred before 2004 and then remained unchanged through 2006–07. The CEP study asked survey respondents to indicate instructional time changes since 2002. Findings from the interviews conducted in the GAO study indicated that changes in instructional time were due to state and district mandated requirements to meet NCLB proficiency standards.

Research conducted within the field of arts education found similar trends. Jacob Mishook and Mindy Kornhaber (2006) were interested in learning how high-stakes accountability was affecting curricular provisions for arts education. Dissatisfied with the snapshot offered by survey studies such as those described above, which do not explain the kind of arts education practice occurring in schools as a result of high-stakes testing, they conducted a qualitative study focused on the state of Virginia, chosen for its strong accountability system. They conducted an interview study centered on 10 arts-focused schools and 8 nonarts-focused schools matched by district, school level (elementary and secondary), and demographics including student income level and minority status, interviewing school principals and occasionally arts coordinators. They found that integration was a prominent strategy for accommodating arts education in the curriculum. They further analyzed the participants' conceptions of arts integration, using Liora Bresler's (1995) categorization of arts integration typically found in schools, the coequal, cognitive approach or the subservient approach (as cited in Mishook and Kornhaber, 2006). In the coequal approach, the art discipline is given equal weight in the lesson with the nonart discipline, maintaining the integrity of art content, skills, and ways of thinking. In the subservient approach, the art discipline is used as a tool in service of the nonart discipline, typically in a superficial manner. Mishook and Kornhaber found that the arts-focused schools were more likely to use a coequal, cognitive approach, while the nonarts schools typically used a subservient approach. Secondly, they found that the schools with a higher student poverty level were more likely to use a subservient arts integration approach, often in the service of test preparation, and that coequal arts integration was less available in high poverty schools. They acknowledged that these findings come from a small sample, but asserted, "If this holds true for a larger sample, this would align with research indicating a greater pressure toward using direct instruction for test preparation among high poverty schools…" (p. 7).

During the 2009–10 school year, the U.S. Department of Education's Institute of Education Sciences and National Center for Education Statistics (NCES) (Parsad and Spiegelman, 2012) conducted a study of the status of arts education (music, visual arts, dance, and drama) in public elementary and secondary schools through surveys to principals, classroom teachers, and arts teachers. While this is a substantial report with comprehensive and extensive findings, due to space restrictions I will highlight only a few of the findings here. The report provides comparisons with the previous NCES study conducted on the status of arts education in the United States a decade earlier (1999–2000). While instruction in music in public elementary schools remained consistent, there was a drop from 87 to 83% for visual art instruction in responding elementary schools. Instruction in dance and drama dropped from 20% of schools in 1999–2000 to 3 and 4% for dance and drama, respectively. For schools in which dance and drama were integrated into other subjects, there was a decrease of 5% for dance and a slight increase for drama. Similarly in secondary schools, the percent of schools providing music instruction remained consistent over the decade, while the percent of schools providing visual arts instruction decreased from 93 to 89%. Among the small percentage of secondary schools providing dance and drama education, there was also a decrease over the decade from 14 to 12% for dance and 48 to 45% for drama. On a positive note, the percent of secondary schools requiring arts coursework for graduation rose from 52 to 57% over the decade.

In relation to the trend of less instructional time in the arts for low-income students described above, the NCES report adds more evidence (Parsad and Spiegelman, 2012). Compared to 94% of public elementary schools without a majority of low-income students offering music instruction, 89% of schools with majority low-income student populations provide weekly music instruction. The comparison is greater at the secondary school level, with 81% of secondary schools with a majority of low-income students offering music instruction compared to 91% for those schools without a high percentage of low-income students. The decrease over the decade, however, is more significant, with a 19% drop in secondary schools with majority low-income student population offering music instruction. For visual arts education in elementary schools, there has been an increase in the percentage of schools with majority low-income students providing art instruction over the decade (from 74 to 80%). However at the secondary school level, there has been a decrease in the percentage of schools with a majority low-income student population providing visual arts instruction over the decade, from 93% in 1999–2000 to 80% in 2008–09. It appears that provisions for arts

instruction have been most impacted at the secondary level across the decade.

Impact of Reduced Provisions for Arts Education

The results of the 2008 National Assessment of Educational Progress for the arts (visual arts and music) indicate a difference in performance among ethnic groups and poverty status. While overall, the aggregate performance in both music and art by eighth grade students was in the midrange on the 0–300 scales used for responding in music and visual art and for creating in visual art, it was less for minority and low-income students. Related to aesthetic education, low-income students scored 28 points lower on the music responding scale and 29 points lower on the visual arts responding scale than those not eligible for free and reduced lunch (National Center for Education Statistics, 2009). The creating scores in the visual arts (creating in music was not assessed) for Black and Hispanic students were lower than the scores of White and Asian students as were the scores lower for low-income students.

In addition to student achievement in the arts, a study by Rabkin and Hedberg (2011) infers what decreased arts instruction at the K-12 level might mean for participation in the arts as adults. Responding to a finding in the 1992 Survey of Public Participation in the Arts (SPPA) that arts education was the strongest predictor of most types of arts participation (excluding arts performance), Rabkin and Hedberg analyzed data from four administrations of the SPPA (from 1982, 1992, 2002, and 2008) to explore that finding. They found that across the four administrations, there was a positive correlation with childhood or adult arts education and attendance at 'benchmark' arts events (classical or jazz music concerts, plays, opera, and dance performances). Arts participation tended to be higher among Americans who also experienced childhood or adult arts education. The analysis also documented a decrease in school-based arts education in childhood from 1982 to 2008, with the peak of the percentage of Americans receiving arts education in childhood in the late 1980s and a sharp decline subsequently. The time period of the decline coincides with the advent of the standards-based and heightened accountability reform movement in the United States. The report also documents the decline in school-based arts education across the four survey administrations to be more pronounced for Black and Hispanic students. The report clearly states that childhood arts education is the most critical for adult arts participation, as most Americans who pursue arts education as an adult had some arts education as a child. They also emphasized that,

> Although there are some free programs and some scholarship programs for needy students, children generally require both a financial commitment from their parents and additional parental support to attend non-school programs. While non-school arts education programs are vital resources in communities all across the country, schools are the only institutions that have the potential to deliver arts education experiences to virtually all children (p. 20).

The significance of this trend is heightened when one examines the correlational research of Catterall et al. (2012) who examined four longitudinal databases to investigate the relationship between arts engagement and positive social and academic outcomes for adolescents and young adults of low socioeconomic status. A sample of their findings include that the majority of youth from low-SES backgrounds but with arts-rich experiences attended college after high school. Also, students from both low and high-SES backgrounds with rich arts experiences are much more likely to show civic-minded behavior such as voting, volunteering, and engagement in local or school politics.

Conclusion

In a democratic country such as the United States that asserts equality as a core value, the uneven provisions of arts education for low-income, Black, and Hispanic students undermines the social reconstructionist philosophies of John Dewey and Maxine Greene that continue to guide aesthetic education in the twenty-first century. While this article provided a focus on aesthetic education in the United States, more research is needed on the status of aesthetic and arts education internationally. Efforts currently underway through the International Society for Education through Art focused on visual art education (http://www.insea.org/), and research agendas presented by the arts education area of the United Nations Educational, Scientific and Cultural Organization will contribute to this effort, presenting cross-cultural comparisons that may provide models of robust aesthetic and arts education for diverse cultural contexts.

Abstract

Attention to emotion and affect is a wide register running through the history of anthropology. Until recently, however, emotions and affect have not often been explicitly articulated as a force in themselves in theories of culture, history, and ways of life. This article traces the history of affect and emotion in anthropology and reveals emergent trajectories for future work. It situates affect and emotion historically and highlights key writings on these themes in cultural, physical, and linguistic anthropology, and in archaeology. Ultimately, it positions affect as a fruitful analytical tool for anthropology and as a generative source of cross-subfield dialogue.

Emotion and Affect as an Analytical Object

In anthropology, attention to emotion and affect is a wide register running through the history of the field. But emotions and affect have not often been explicitly articulated as a force in themselves in theories of culture, history, and ways of life. They have, instead, been taken to be natural and universal states of being, atmospheric backgrounds to life, pervasive but subterranean and coded forces, or the secondary constructed effects of an order of representation or structures of power including class, race, gender, ethnicity, religion, sexuality, and the state. Until the recent emergence of an anthropology of emotion and affect and the replacement of theories of cultural wholes with theories of assemblages, force fields, and micropolitics, emotion and affect were rarely recognized as anthropological objects, but were treated instead as idioms for the then more obviously significant phenomena of structures of power and sociality. Broad affective questions of force, impact, and intensity have long been alluded to in studies of known anthropological objects such as violence, attachment to place and identity, or resistance and revolution. The emotional or affective force of social–cultural orders has been approached through studies of kinship, ritual, hierarchy, exchange, honor, and shame systems, and specific traditions and institutions such as head-hunting and veiling.

These investigations have taken place, for the most part, within a dynamic that pits close contact against distant observation and personal feelings against public knowledge. The idea that perspective and theory are themselves essentially produced through an originary act of distancing has been haunted by affective and emotional marginalia. Raymond Williams's (2001) work on structures of feeling has been long accepted and used to specifically address the qualities of emergence and the residual surrounding reductive models of structure in itself. However, even the relatively recent ethnographic work of anthropologists such as Renato Rosaldo (1993), Michelle Rosaldo (1980, 1984), Jose Limon (1994), and Steven Feld (1982) operated as eruptions in the field that drew strong reactions when they made emotion and affect the explicit object of analysis. These and other scholarly works articulated with both the writing culture critique (Clifford and Marcus, 1986) and feminist interventions that also began to directly document the power of affect and emotions (see, for example, Lutz and Abu-Lughod, 1990).

The generative clash between structure and history, observation and participation, and expert knowledge and the felt impact of everyday life opened divergent trajectories for current anthropology. Anthropology is still driven by a dynamic between emergent phenomena, complex causality, and an attention to the felt presence of historical events and present moments, on the one hand, and an attunement to the clarity of structures, institutions, cultural categories, norms, and conventions on the other. Work on affect and emotions is both symptomatic of this dynamic and itself an emerging field of theory and ethnographic experiment. Most recently, the development of affect studies in cultural studies (Berlant, 2008, 2011; Gregg and Seigworth, 2010) has established a strong affect studies trajectory in anthropology (Mazzarella, 2009; Stewart, 2007, 2010, 2011).

Emotion and Affect Studies in the Four Fields

In cultural anthropology, work on the emotions has long been grounded in cultural relativism, interpretive models, and social constructionism. Questions of emotion and attachment have been central to debates on the role of ethnography and the nature of the ethnographer–research subject relation. Fieldwork has been identified as itself an emotional experience that hinges on efforts to approach the experience of others and the variety of forces that shape the broad outlines of a way of life and remain resonant in daily life and conventions. Approaches to cultural expressivity and form have demonstrated the emotional-affective register of meaning emergent in music, sound, poetry, dance, storytelling, and the performativity of everyday life.

Within cultural anthropology, emotions are often described as either the pliant material upon which acculturative and cognitive forces operate, or the energy which animates otherwise lifeless cultural forms. The explicit attention to emotions as analytical objects began with a treatment of emotions as cultural categories, even a master western cultural category, in the effort to advance a cross-cultural understanding of emotion. Emotions have also often been described as an unconscious normative force. Michelle and Renato Rosaldo's work made emotions central to the theory of the situated subject and situated ethnography. This made way for the predominance not only of native ethnography, but also of new models of positioned epistemology, including emotional thinking, embodied

knowledge (Lutz and White, 1986), and a political imperative to draw on personal experiences, proximity, and intimacy in defining and exploring the subjects and objects of fieldwork. The work of documenting named or categorically represented emotions, such as grief, anger, hope, fear, loyalty, and love, expanded into analysis of structures of feeling and the phenomenology of lived states of being including work on nostalgia, utopianism, religious piety, structures of reciprocity, nationalism, belonging, and visceral attachments.

From an evolutionary perspective, physical anthropologists treat nonhuman emotions and affects as critical components of natural selection. Evolutionary theory, including Charles Darwin's *The Expression of Emotion in Man and Animals*, argued that emotions are a critical component of natural selection as adaptive responses to social and environmental opportunity and threat. It is theorized that social emotions evolved to motivate adaptive social behaviors. Primate behaviorists have long noted a complex range of physical displays of emotion including fear, grief, happiness, anger, and disgust. Emotions and their expressive body language have been taken to be strong evidence of the lines of human–nonhuman primate evolution.

Physical anthropologists have become increasingly interested in the study of emotions in recent decades. New work in neuroscience, primatology, and cognitive psychology has generated approaches to emotional control, social bonding, romantic love, and empathy among primates. Neuroimaging is now used to investigate evolutionary ancient parts of the brain. Neurobiological theories focus on arousal patterns in which neurochemicals (such as dopamine, noradrenaline, and serotonin) step up or step down the brain's activity level, as visible in body movements, gestures, and postures. Such paleocircuits are neural platforms for bodily expression. It is thought that there are certain activities in brain areas related to attention and motivation, especially the limbic system, which includes the hypothalamus, cingulate cortex, hippocampi, and other structures. New theories of the science and biology of emotions have generated innovative understandings of the linkages between behavior and emotions. Some also suggest implications for the ethical underpinning of human life and morality as an essential part of primate nature (De Waal, 2003).

Linguistic anthropology addresses the force and effects of language dominance, loss, and revival, the affective ties that enable language socialization, and the emotional registers of class, gender, race, ethnicity, and other hierarchies and identity markers in language and its performance. The production and comprehension of feelings are basic for language acquisition. The role of emotion in language has been addressed as a communication code including phonological, syntactic, and pragmatic as well as semantic elements. Emotions, like language itself, can be seen as having a semiotic system. Somewhat outside the purview of semiotics, utterances can also be seen as having an affective component, or an impact that moves between and across subjects, expressive forms and situations, and language structures. Linguistic anthropologists have taken up questions of the circulation and the transformative qualities of language forms. James Wilce (2009) advanced an analytical attention to 'feelingful language' as an embodied practice that avoids reduction of feelings to the level of discourse. Paul Kockelman (2011) takes a semiotic approach to theorizing the relationships between ontology, selfhood, and affect, arguing against an analytical separation of these three dimensions.

Archaeological theories of state formation rely on evidence of violence and conflict. They are also attuned to the levels of intensity of historical events and therefore to the study of affect as a register of historical force. With a strong base in the analysis of materials, archaeologists have also launched a powerful critique of radical constructionism; forms of agency and identity are not treated as ciphers through which other social and cultural forces are inscribed, but remain concretely embodied in practices, environments, and strategies of living. Recent theories of prehistorical affective structures and the production of emotions have critiqued naturalized frameworks for feelings and the theoretical shorthands that framework has enabled. One strand of this work calls for much more detailed and precise studies of individual and variable selves, questions of intentionality, and attention to embodied emotional experiences (Meskell, 1996; Tarlow, 2000). Another strand of contemporary archaeological theories of affect and emotion locates them in the material infrastructure of social spaces (e.g., architecture, lighting, and sensuous qualities) and movement (the corporeal staging of particular channels of experience). This work begins with the insight of new materialism that the sensuous quality of things and bodily presence are both, and coconstitutively, productive of perceptions, experiences, and atmospheres (Harris and Sørensen, 2010; Tilley, 1996).

Affect Studies in Anthropology

Emotion studies in anthropology tended to be grounded in questions of culture and cognition and to refer to named states such as anger, grief, love, or shame, which were experienced by subjects and charged with the judgments and norms of a social–political–cultural–representational order. That is, in emotion studies feelings are part of a cultural–political apparatus. Affect studies suspends the assumption of a cultural whole, taking a step back to questions of the intensities and felt impacts of a broad assemblage of circulating forces, which remain disparate though, at times, articulated. Affect studies takes as its object these intensities and impacts and their circulations and articulations. Often strongly influenced by the work of Deleuze and Guattari (1987) and a line of philosophical influence including the work of William James, Nietzsche, and Spinoza, affect studies define affect as the capacity to affect and to be affected. Where emotions are presumed to be a form of social construction – named, value-laden states of being closely tied to a politics of representation – affect is a domain, register, or machinery of intensity, speed, rhythm, and emergent form. It is the force that moves bodies of all kinds – human bodies, bodies of thought, institutions, populations, or bodies of force – into and out of states of being. Affect is not ontologically distinct from or secondary to cognition or meaning. Affect theory assumes not that an abstracted order of meaning creates worlds by instantiating and reproducing itself, or that the mind and its states of consciousness get the world right or wrong, but rather that the processes of emergence or becoming are complex compositions assembled out of bodies, materialities, scenes, events, and the substantial micropolitics

of force fields saturating everything from institutions to collective moods.

The objects of affect theory are simultaneously very abstract and very concrete. They are relational, in motion, and about transversal, transduction, and resonance. An affective event is an increase or decrease in the ability of the body to act. Brian Massumi (2002) theorizes it as the sensation produced in the encounter of bodies and forces and as the tipping point between the potential and the actual – the energy of something moving into being. Its objects are things in the process of becoming something else or forms that are emerging and dissipating.

Affect studies in anthropology pulls into alignment with Foucaultian and Nietzschian articulations of the intimate relations between knowledge and power. These theories focused intellectual projects on the conditions of the emergence of forms built into the conduct of life. The coming into being of forms in the details of daily life moves beyond the oppositions of fabulated/real, structure/agency. Structure takes place as singular events saturated with everyday sensibilities. Politics is not reducible to a communal consciousness or a neatly conceptualized ideology but takes place as intensities of all kinds and in various registers. Agency is not the clear and intentional act of a subject but an energetics. The anthropological objects of affect studies now include, for example, the pressure points of life, the structures of impact and attention being laid down in microbiopolitics, new sensory registers, and the systematic engineering of affect.

Capitalism, in affect studies, is itself a set of constantly performing relays and junctions that are laying down new affective fields of potentiality and closure. Nigel Thrift's (2004, 2011) work carefully outlines the swollen role of affect in the complex dynamics of contemporary capitalism and concomitant shifts in forms of knowledge and experience. In affect studies, systems of power are not flat sets of beliefs and effects but layered, irregularly matched, distinctive capacities that become possible and perhaps only partially legible. Power as system can be seen as the composition of dense loops between TV, cinema, philosophy, neurophysiology, and everyday life that constitute a neuropolitics (Connolly, 2002). This perspective requires new forms of critique and new modes of ethnographic attention. Latour (2005) and other nonrepresentational theorists replace evaluative judgment with an ethical–political attunement that tries to instill generosity toward a world by attending to its infrasensible knowledges.

Politics resides not in the rational subject but in the nonsubjective sensuous mimetic potential of the interlocking patterns, thresholds, and triggers of emergent, transversal bodies (Protevi, 2009). From the perspective of affect as a transductive machinery of relay, new political registers place questions of power and force in the contexts of ways of living through situations and the composition of worlds out of whatever is happening, presenting a fuller view of what is at stake for people in everyday life. Violence and conflict are seen not as exceptional moments of crisis, but as integral parts of a social world comprised of fault lines and edges. Social and cultural ties are not presumed by association with abstracted structures, but have to be tracked as moments of affinity and difference emergent in performance. The questions shift away from tracking the effects of the cultural modeling of a given reality to attending to the processes of social and material life: how places, practices, identities, and forms of cohabitation become lived worlds, how people sense the world they inhabit, how people come to recognize themselves, and their affinities with others and things (Ingold, 2000).

Emergent Anthropological Practices

Affect studies opens avenues to approach enduring anthropological questions: how to trace the forces that traverse the individual and the collective, and person, place, and thing; how to track and model complex articulations and assemblages; how to describe forms of signification that extend beyond code and representation and beyond individual consciousness; how to attend to sensory impacts and forms of knowledge; how to approach questions of force and intensity in ethnographic accounts; and how to build models of meaning grounded in the emergent practices of situations of the present. Affect studies is closely articulated to emergent efforts to address these questions with new paradigms including nature–culture studies, science studies, new materialism, posthumanism, and public culture.

In ethnography, affect studies is among the efforts to retheorize the anthropological object through more nuanced and prismatic approaches to the angles of persons, performances, bodies, atmospheres, rhythms, environments and social, affective, material, and institutional infrastructures. Attention to affect produces an attunement to the potential or emergent forces in a scene and becomes a means of recognizing the not quite visible yet forceful processes at work in even the most seemingly abject, private, or embodied iterations. For example, in *My Cocaine Museum*, Michael Taussig, describes the structure of feeling of a present moment in Colombia when the agribusiness boom has suddenly just stopped:

> … now there is no work at all …. That's all over now. The idea of work work. Only a desperate mother or a small child would still believe there was something to be gained by selling fried fish or iced soya drinks by the roadside, accumulating the pennies. But for the young men *now*, there's more to *life*, and who really believes he'll make it past 25 years of age? … At fourteen these kids get their first gun. Motorbikes. Automatic weapons. Nikes. Maybe some grenades as well. That's the dream. Except that for some reason it's harder and harder to get ahold of, and drug dreams stagnate in the swamps in the lowest part of the city like Aguablanca, where all drains drain and the reeds grow tall through the bellies of stinking rats and toads. *Aguablanca*. White water. The gangs multiply and the door is shoved in by the tough guys with their crowbar to steal the TV as well as the sneakers of the feet of the sleeping child; the *bazuco* makes you feel so good, your skin ripples, and you feel like floating while the police who otherwise never show and the local death squads hunt down and kill addicts, transvestites, gays – the *desechables*, or "throwaways" – whose bodies are found twisted front to back as when thrown off the back of pickups in the sugar cane fields owned by but twenty-two families, fields that roll like the ocean from one side of the valley to the other as the tide sucks you in with authentic Indian flute music and the moonlit howls of cocaine-sniffing dogs welcome you.
>
> (2004: p. 19)

This kind of affective ethnographic writing requires a supple attention and the capacity to imagine trajectories and follow tendencies. When the object of anthropological analysis is the levels of sense, rhythms, aesthetic forms, and energetics, of what

is emerging or falling apart, ethnography takes as its object the generativity of things, ontologies of multiplicity, planes of expressivity, the ways that a tendency takes on consistency, what is being magnetized in a thrown-together thing, what frictions run its machinery, and what happens when things suddenly stop.

Ethnographies of affect have yielded new concepts of ways of living through situations. Affect emerges at the juncture (and disjuncture) of personal experience and public circulation (Gregg and Seigworth, 2010; Mazzarella, 2009). Bodies not only unfold in and inhabit the world through contingent lineages, potentialities, entanglements, and aspirations but they actually acquire their very form through their affective engagements (Ahmed, 2010; Povinelli, 2006; Stewart, 2007, 2010). The entanglements between bodies, discourse, and history are bound up with currents of expectations, landscapes, and histories (Povinelli, 2006); dispositions accumulate (Stewart, 2010); in the charged territory between the potential and the actual, seemingly broken bodies result from a complex constellation of potentialities unfolding over time (Biehl, 2005); precarious ways of living through things that produce prolific strategies and fantasies (Berlant, 2011); affect generates worlds (Stewart, 2010).

Affect is a lens for approaching social worlds and lived experiences as ongoing processes, highlighting partiality, flux, and contingency. It is perhaps particularly well suited to examine the dynamics at work in logics of materiality, cohesion, rupture, or the exhaustion of forces and forms. Cultural anthropologists have used the concept of affective labor to probe the relationships between feelings, work, capitalism and, often times, gender in contemporary life (Hardt, 1999). Elizabeth Povinelli (2011) analyzes the temporality, ethics, and quasi events of affective attachments to probe the ordinariness of isolation and abandonment. William Mazzarella (2009) argues that affect is a necessary moment of any modern institutional practice with aspirations to public efficacy. That is, modernity has always been structurally affective; any social project that is not imposed through force alone must be affective in order to be effective. Lauren Berlant (2011) has elaborated how affective structures shape realities, generating frames in which certain types of possibilities come into being. As work on affect probes the contingent lineages of contact and affinity, gesturing toward moods and collective sensibilities rather than causation, it adds critically important nuance and texture to such traditional frameworks as political economy, structural violence, or biopolitics (Biehl and Locke, 2010). As anthropologists continue to grapple with how to produce theories of large-scale social experience while accounting for the inner worlds and daily lives of individuals, work on affect offers new tools for a simultaneous analysis of both poles (Biehl, 2005; Biehl and Locke, 2010; Das, 2006; Povinelli, 2006).

Conclusion

The long impasse in anthropology of the categorical opposition between biology and culture has played a role in naturalizing emotions to the extent that they are associated with the body. This has also limited approaches to knowledge, agency, and sociality. Where thought and knowledge are stereotypically associated with intentionality and logic, and consciousness with agency, body, and emotion are imagined as both untamed and too tamed, outside the order of representation that stands in as a shorthand for culture and society and also beneath recognition as the banal and all-too-well known. Until the relatively recent surge in interest regarding an anthropology of emotions, they were presumed to be universal aspects of the human experience that were both central to an individual's interior world and also transparently intelligible across cultures (Lutz, 1986). Studies of emotion and affect have produced a middle ground between biology and culture, and the individual and the social. Analyses of affective structures have expanded the reach and depth of studies of nationalism, violence, belonging, and affinity on a global scale and across virtual worlds, parsing out the resonances of distinctly dispersed, yet complexly interconnected, modes of life and practice.

Linking to interdisciplinary work in science studies and nonrepresentational theory, affect theory has been used to posit and produce an alignment between theory and the compositional attunement through which people and things venture out into reals. Reals, in this view, are not the kind of thing that an order of representation simply organizes as truth and dominates, but "transversal arrays of qualities or activities which, like musical refrains, give order to materials and situations, human bodies and brains included, as actions undertaken act-back to shape muscles and hone senses" (Anderson and Harrison, 2010: p. 8). This is not the work of imagination on dead matter but a "mattering (that) is about the (contingent and temporary) becoming-determinate (and becoming-indeterminate) of *matter* and *meaning*" (Barad, 2010: p. 254). This is a world built out of difference and repetition (Deleuze, 1994), composed of potentiality and loss (Berlant, 2011), and leaning toward entities that are both present and absent – atmospheres, affects, virtual memories, hauntings, that are themselves moments of endurance (or not), instants of the holding together of the disparate itself (Doel, 2010). This is a world that is not reducible to its representation, or what we know of it (Anderson and Harrison, 2010). One that is potentially a newly capacious object for the distinctive lines of approach of archeological, linguistic, physical, and cultural thought and method.

Affect-Regulation Motivation

Michaela Riediger, Max Planck Institute for Human Development, Berlin, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Affect-regulation motivation refers to how people want to influence their affective experiences. It is typically prohedonic, but can at times also be directed at the enhancement or maintenance of negative, or the dampening of positive affect. This article reviews the current state of research on the following questions: Why are psychologically healthy people occasionally inclined to seek negative, or to dampen positive affective experiences? Does such contra-hedonic motivation require cognitive resources? Are there individual differences in pro- and contra-hedonic affect-regulation motivation? What roles do the individual's age, personality disposition, or cultural background play in this respect?

Affective states – such as feeling angry, downcast, excited, or content – are an integral aspect of human experience. They direct people's attention, guide judgments and behaviors, and provide, when expressed, communicative signals to others that can regulate social interactions. Affective states thus serve essential functions. Being able to influence – or regulate – the experience and expression of affective states, however, is equally important. Terminating negative affective states once their informational, behavioral, or communicative functions have been fulfilled, for example, is necessary for healthy psychological functioning (Larsen, 2000). In addition, many life tasks – from forming and maintaining social relations to successfully pursuing a career – require the ability to influence the intensity and expression of positive and negative affective experiences.

For a long time, the assumption prevailed that affect-regulation efforts are invariably motivated by a desire to enhance the individual's affective well-being. In the past two decades, however, awareness has grown that this is not always the case. Studying affect-regulation motivation can thus contribute to a better understanding of individual differences and within-person fluctuations in affective experiences.

This article reviews the current state of research on affect-regulation motivation, after first clarifying some basic definitional issues.

Some Definitional Issues

Affect, Emotion, and Mood

The term affect is used in this article as an overarching category that subsumes emotions and moods (Gross and Thompson, 2007). Both emotions and moods are experiential entities that are characterized by inner feelings, accompanying physiological processes, and that can be outwardly expressed. While emotions are typically elicited by specific events in the individual's environment or by thoughts about those events, moods tend to have less specific causes and to be related more to the individuals' internal resource capacity (e.g., their level of fatigue). In addition, emotions tend to be more intense than moods, but more short-lived, and to have clearer onset and offset points (e.g., Larsen, 2000). Despite these differences, boundaries between emotions and moods are not clear-cut. This can make empirical differentiation difficult, particularly in studies that assess naturally occurring affective experiences. This explains why many of the studies reviewed below were not able to distinguish between emotions and moods explicitly. In these cases, the umbrella term affective experience will be used.

Pro- and Contra-Hedonic Affect-Regulation Motivation

Affect regulation refers to ways individuals influence the experience and expression of affective states. It often occurs without awareness and intentional effort, but can also be deliberately initiated by the individual. Affect regulation can take many different routes. Avoiding affect-eliciting situations, reappraising their significance, or suppressing outward expressions of inner experiences are but a few examples. Irrespective of their specific manifestation, however, all of these regulatory behaviors are preceded and fundamentally shaped by motivational processes.

Affect-regulation motivation determines the direction of a given affect-regulation effort. It can be directed at the maintenance, enhancement, or dampening of affective experiences and expressions. In everyday life, most people likely do not contemplate their affect-regulation motivation much, if at all. Research has shown, however, that when asked to do so, they can report on it (e.g., Mares et al., 2008; Riediger et al., 2009; Wood et al., 2009). Affect-regulation motivation thus seems to be at least partly accessible to individuals' introspection.

Historically, the assumption long prevailed that motivation of psychologically healthy people in general, and their affect-regulation motivation in particular, are guided by a prohedonic principle. That is, psychologically healthy people were expected to be generally motivated to enhance or maintain positive (pleasant) affective states, and to avoid or dampen negative (unpleasant) affective states (for a discussion of relevant historical positions, see, e.g., Erber and Wang Erber, 2000). Contra-hedonic tendencies were assumed to occur only in mental pathology. Indeed, psychological disorders can involve such symptoms as the deliberate inflicting of injury and pain upon oneself, or a pathological desire to maintain or enhance negative affective states. Recently, however, awareness has grown that contra-hedonic motivation can also occur in nonclinical populations. Although prohedonic affect-regulation motivation is in fact

predominant in psychologically healthy individuals, there can also be occasional exceptions.

Empirical evidence stems, for example, from an experience-sampling study with participants ranging in age from adolescence to old adulthood (Riediger et al., 2009). Participants reported, on average 54 times in 3 weeks, whether they currently wanted to dampen, enhance, or maintain each of six positive and negative affect facets (i.e., feeling angry, downcast, anxious, interested, joyful, and content). The majority of reported affect-regulation motivations were indeed prohedonic, that is, directed at the enhancement or maintenance of positive affect or the dampening of negative affect. Interestingly, however, there were also occasions when participants reported wanting to maintain or enhance negative affect or to dampen positive affect. Across the entire sample, such contra-hedonic motivations were reported, on average, in 15% of the measurement occasions.

Everyday observation also confirms that people are occasionally inclined to forego positive feelings, or to seek or maintain negative feelings. Examples include listening to plaintive music to indulge in sadness, seeking to put oneself into a somber mood before delivering bad news, or trying to work up a state of anger before attempting to assert one's interests in an argument.

The purpose of this article is to review the current state of research on affect-regulation motivation in nonclinical populations. The first part zeros in on the phenomenon of contra-hedonic motivation. It addresses the question why psychologically healthy people might occasionally be inclined to seek negative, or to dampen positive affective experiences, and summarizes research on cognitive resource demands of such contra-hedonic motivation. The second part focuses on individual differences in pro- and contra-hedonic affect-regulation motivation. Evidence of the respective role of individuals' age, traits (personality, self-esteem), and cultural context is reviewed. This article concludes with an outlook on open research questions that need to be resolved in future research.

Possible Reasons for Contra-Hedonic Motivation

Two complimentary explanations for occurrences of contra-hedonic motivation in nonclinical populations are currently discussed. One perspective argues that contra-hedonic motivation may arise when positive experiences accompany apparently negative affective states, that is, when the affective episode is mixed. A complementary account proceeds from the idea that contra-hedonic motivation may occur in situations in which negative affect is useful, or positive affect disadvantageous for the individual. These two positions will be referred to as the mixed-affect and instrumental-affect perspectives below.

The Mixed-Affect Perspective

Affective experiences are not always unequivocally positive or negative in nature. Occasionally, affective episodes may entail a blend of various affective states of opposing valence. For example, people can experience sadness and happiness simultaneously, such as during nostalgic reminiscence; or fear and excitement, such as when engaging in risky activities. Other combinations of affective states of opposing valence can co-occur as well (e.g., disgust and amusement). It is also possible that a given affective state is not accompanied, but followed by a state of opposing valence (e.g., elation followed by embarrassment). The mixed-affect perspective proposes that anticipated or actual mixed affect might motivate individuals to seek or maintain an apparently negative affective state because they associate enjoyable or otherwise positive aspects with it, or, vice versa, to dampen an apparently positive affective state because they associate unpleasant aspects with it as well.

Evidence in line with this perspective stems from the experience-sampling study mentioned above (Riediger et al., 2009). Participants in this study were more likely to report the contra-hedonic motivation of wanting to maintain their momentary negative affect in situations where they experienced mixed affective states, that is, simultaneous positive and negative affect that were both more intense than the individual's respective averages.

Further support comes from a series of studies reported by Andrade and Cohen (2007). These studies showed that students who liked to watch horror movies were more likely to experience both negative and positive affect while watching, whereas persons who avoided horror movies tended to only experience negative affect. Interestingly, the pattern and intensity of negative affect (e.g., fear) while watching did not differ between persons who liked to watch and those who avoided horror movies. This speaks against the possibility that individuals who look for apparently aversive experiences appraise them in a more positive manner. It has also been argued that people may seek negative experiences because of the relief or pleasure that follow in the aftermath. This explanation, however, did not hold in the studies by Andrade and Cohen (2007), where such feelings of relief were greatest in participants who avoided these types of films. Instead, these studies suggest that the apparently contra-hedonic motivation of wanting to view horror movies is associated with positive affective experiences that accompany fear when watching.

The Instrumental-Affect Perspective

The instrumental-affect account of contra-hedonic motivation posits that affective states can be helpful or harmful for an individual's goals, depending on the particular context. This idea is commensurate with evolutionary theories that propose that emotions evolved as multicomponential response systems because they prepared for the fast execution of adaptive behaviors, communicated important information to conspecifics, and thus enhanced chances of survival. A classic illustration of this idea is the instrumental value of fear in threatening situations. The experience of fear, along with the accompanying physiological and cognitive processes – such as enhanced autonomic arousal and attentional narrowing – prepares the individual for rapid engagement in adaptive action, such as flight. The expression of fear furthermore signals danger to others, who can then also get set to seek safety quickly. Fear can thus be helpful in situations that require the avoidance of threats or dangers. In other contexts, however, fear can be detrimental to the individual's interests. When desired objects are available in the absence of immediate danger, for

example, fear might hamper engagement in the approach behavior that would be necessary to obtain the desired item.

Affective states have retained their context-dependent utility until today. Although they may rarely be relevant for immediate survival anymore, they can nevertheless have implications for the attainment of an individual's goals. Central to explanations of contra-hedonic motivations from an instrumental-affect perspective is the observation that there can be situations where negative affect is instrumental for, and positive affect detrimental to an individual's goals. Anger, for example, can help individuals to assert their interests in an interpersonal confrontation; and expressing guilt or shame after wrongdoing can help individuals to be more favorably perceived and better liked by other persons. Joy, on the other hand, can be inappropriate when delivering bad news. Affective states have also been associated with how individuals process information. Although positive affect can facilitate performance in tasks that require creativity, flexibility, or holistically focusing on the overall picture, it is less helpful for chores that require accurate and analytic processing of complex details, or the application of intricate rules. The latter tasks are facilitated more by negative affect of moderate intensity (e.g., Clore et al., 2001). Instrumental-affect accounts therefore propose that contra-hedonic motivation may derive from people's being (consciously or unconsciously) strategic in seeking affective states that are instrumental in a given context.

Research by Erber and colleagues supports this idea. In various studies, either happy or sad mood was induced in participants who were then led to believe that they were about to work on a task either with a stranger, with their own romantic partner, or alone. Prior to the task, participants indicated whether they preferred to read a humorous, sad, or neutral newspaper story. Anticipation of working on a task together with a stranger (vs expecting to work alone) led to an enhanced preference for mood-incongruent newspaper stories, suggesting that participants were motivated to neutralize the induced positive or negative mood. This was not the case, however, when participants expected to work with their romantic partner (Erber and Wang Erber, 2000).

The authors interpreted these findings by arguing that neutralization of positive affective states can be helpful when interacting with strangers, even though it is contra-hedonic, because it unburdens the individuals from possible distractions by their affective state, and thus frees cognitive capacity to attend to the affordances of the unknown social situation. It also reduces the likelihood of having or displaying socially inappropriate affect, which might otherwise lead to unfavorable evaluations by the unknown interaction partner. In other social contexts, such as when interacting with one's romantic partner, in contrast, attenuating positive affect might not be instrumental and may even be detrimental to the relationship (Erber and Wang Erber, 2000).

Various studies by Tamir and colleagues demonstrated that people might seek negative affect when they expect it to be instrumental for the pursuit of their current goals. Participants in two studies reported by Tamir and Ford (2012a), for example, were assigned either a confrontational or a collaboration goal in an interpersonal negotiation task. Participants with the goal to confront (vs collaborate with) their negotiation partner showed a stronger preference for anger-inducing activities in anticipation of the negotiation (e.g., were more likely to prefer recalling past experiences in which they felt angry). Further studies also demonstrated similar contra-hedonic tendencies in other task contexts. For example, enhanced preferences for fear-inducing activities were observed when participants expected to play a computer game in which their goal was to avoid threatening elements (Tamir and Ford, 2009), whereas enhanced preferences for anger-inducing choices were observed when participants expected to play a computer game in which the task was to shoot virtual enemies (Tamir et al., 2008). The authors argued that participants sought negative affect in these studies because of its instrumental value for the pursuit of their assigned goals. For example, in the negotiation studies (Tamir and Ford, 2012a), participants who were set the task of confrontation (vs collaboration) with their negotiation partner were more likely to expect anger to be helpful in their negotiations. Furthermore, selection of anger-inducing activities did indeed lead to more intense feelings of anger during the negotiation, which in turn was associated with better negotiation outcomes in the confrontation condition (similar findings were observed in other task contexts as well, Tamir et al., 2008).

Recent evidence further suggests that knowing when negative affective experiences can be useful for, and when positive experiences can be detrimental to one's goals, is not only associated with better specific goal progress, but also with higher levels of emotional intelligence (Ford and Tamir, 2012) and better psychological adaptation more generally. Student participants rated the extent to which they believed feeling anger or happiness would be useful for them in various confrontational and collaborative situations. The more participants perceived anger as being potentially useful in confrontation situations, the better their psychological well-being, life satisfaction, perceived social support, and subjective health was, and the higher their academic achievement in college was. In contrast, the more participants regarded happiness as potentially helpful in confrontations, the lower they scored on several of these indicators of adaptive functioning. This association pattern was reversed (though overall weaker) for perceptions of useful emotions in collaboration situations (Tamir and Ford, 2012b).

Cognitive Demands of Contra-Hedonic Motivation

Research in the tradition of the instrumental-affect perspective demonstrates that contra-hedonic motivation can be helpful for the individual. This, however, appears to demand cognitive resources. In the experience-sampling study by Riediger et al. (2011), participants not only reported their momentary affect-regulation motivation, but also completed two trials of a working-memory task at each measurement occasion. While prohedonic motivation was only weakly associated with within-person fluctuations in working-memory performance, the association of contra-hedonic motivation and working-memory performance was substantially more pronounced: The more contra-hedonic motivation participants reported, the lower their momentary working-memory performance was. These effects of contra-hedonic motivation

on working-memory performance could not be attributed to lack of effort, or to differences in other individual or situational characteristics.

The authors argued that the reason for these findings could be due to the effort required to overcome one's prevailing prohedonic orientation, which necessitates the allocation of capacity. Consequently, the capacity remaining for the simultaneous processing of another resource-intensive task – storing and manipulating information in working memory – would be reduced in situations with contra-hedonic motivation. Prohedonic motivation, which is the predominant orientation in psychologically healthy individuals, in contrast, might proceed more automatically in comparison and hence require fewer cognitive resources.

Individual Differences in Pro- and Contra-Hedonic Affect-Regulation Motivation

Affect-regulation motivation not only varies across situations, as discussed so far, but also differs substantially between individuals. Below, research findings are summarized that elucidate the roles that people's age, their personality disposition, and their cultural background play in this respect.

Age-Related Differences

Evidence abounds that day-to-day affective experiences differ between individuals from different age groups. Adolescents, for example, typically experience relatively more affective turmoil and relatively more frequent negative affective states than adults. Across adulthood, typical patterns of age-related differences also emerge. Healthy older adults characteristically report more stable and more positive affective states in their everyday lives than younger adult age groups do, and affective well-being appears to decline only at the very end of life (for a review of available evidence, see Riediger and Rauers, 2014).

The psychological mechanisms underlying these age-related differences in affective experiences are not yet fully understood. It has been argued, however, that some of these differences might be brought about by variations in people's affect-regulation motivation (Riediger et al., 2009). According to this argumentation, part of the negative affectivity that is characteristic of adolescence, and part of the positive affectivity that is characteristic of old age, may be actively sought and maintained by the individual, either deliberately or unconsciously.

Empirical evidence supports this assumption. Riediger et al. (2009, 2014), for example, investigated affect-regulation motivation in the everyday lives of participants ranging in age from 12 to 86 years. Contra-hedonic motivation was considerably less prevalent than prohedonic motivation in all investigated age groups. There were, however, pronounced age differences. Adolescents reported contra-hedonic motivation most frequently, namely, in about 25% of the measurement occasions. There was a steep decrease in the prevalence of contra-hedonic motivation between the adolescent and the young adult participants, and a further decline throughout the adult subsamples into old age. Prohedonic motivation, in contrast, showed an opposite prevalence pattern. It was least prevalent among adolescent and young adult participants, and most prevalent in later adulthood.

A corresponding picture of age-related differences emerged in a study where 18- to 82-year-old participants reported how much they sought or avoided several affective experiences in their everyday lives, and how much they regarded these experiences as useful or valuable (Mares et al., 2008). Again, preferences for negative affective experiences were most pronounced among the youngest participants, whereas preferences for positive affect and emotional stability increased throughout adulthood. Further empirical support derives from studies on age differences in entertainment use. For example, younger adults were more likely than older adults to report that they liked movies that elicit sadness or fear, while older adults were more likely to prefer heart-warming movies (Bartsch, 2012; Mares et al., 2008).

What might be the reasons for these age differences in affect-regulation motivation? The relatively high prevalence of prohedonic motivation in older adulthood is in line with the theoretical claim that the shrinking horizon of time-to-live shifts older people's motivations toward wanting to maximize their affective well-being in the here and now (Carstensen et al., 2003). The age-related increase in prohedonic motivation might thus be instrumental for the attainment of older adults' affective goals. Analogously, the relatively higher prevalence of contra-hedonic motivation in adolescence might be helpful for tackling the developmental tasks of that life phase. Repudiating prevailing hedonic conventions, for example, might put adolescents in situations in which they have to deal with negative emotional experiences. This, in turn, might help them to establish emotional autonomy from their parents, affirm a sense of maturity, or refine their self-regulatory competencies. It might also be a means to explore the range and depths of possible experiences, which could help adolescents on their way toward developing their own sense of identity (Riediger et al., 2009).

The mixed-affect perspective can also contribute to an understanding of age-related differences in affect-regulation motivations. The studies by Riediger and colleagues, for example, showed pronounced age-related differences in the prevalence of mixed-affective experiences that followed the same pattern as those of contra-hedonic motivation: Both mixed affective experiences and contra-hedonic motivation were most frequent among adolescents, and least prevalent among older adults (Riediger et al., 2009, 2014). Importantly, this pattern of age-related differences was not restricted to participants' self-report, but was also reflected in implicit representations of affect valence as assessed with implicit association tests. Compared to adults from various age groups, adolescents implicitly associated positive affect least distinctively with pleasantness (vs unpleasantness) and unhappiness least distinctively with unpleasantness (vs pleasantness). Furthermore, the less differentiated people's mental representations of affect valence were, the more likely they were to report mixed affect and contra-hedonic motivation in their everyday lives (Riediger et al., 2014).

Trait-Related Differences

Evidence of trait-related differences in people's affect-regulation motivation has been obtained most systematically with regard to people's personality and self-esteem.

Personality

The two personality traits that are currently best researched in this respect are extraversion and neuroticism. Highly extraverted individuals are strongly oriented toward, and influenced by, their social environment. They actively seek out opportunities to interact with others, are talkative, assertive, and excitable. People scoring high on neuroticism tend to easily perceive situations as threatening or difficult, and to react strongly to them. They are prone to moodiness and irritability.

Numerous studies have demonstrated that extraversion and neuroticism are related to systematic differences in people's affective lives. While extraversion is associated with a higher propensity to experience positive affect, neuroticism is characterized by a susceptibility to experience negative affect (for a review of findings, see Ng and Diener, 2009). It has been argued that part of these affective differences may be driven by variations in people's affect-regulation motivation. In line with this idea, results from various studies suggest that the higher people score on neuroticism, the less motivated they are to ameliorate negative affective experiences. In contrast, the higher individuals score on extraversion, the more motivated they are to reduce or eliminate negative affective experiences, and to seek or maintain positive affect (e.g., Kämpfe and Mitte, 2009; Ng and Diener, 2009).

Tamir demonstrated that these personality differences in affect-regulation motivation are particularly evident in situations of effortful goal pursuit. Across a series of studies, extraversion was predictive of a higher motivation to seek out happiness-inducing experiences in anticipation of effort-demanding tasks (e.g., giving a speech), but not in anticipation of undemanding situations (e.g., listening to music, Tamir, 2009a). Similarly, neuroticism was predictive in various studies of a higher motivation to increase worry in anticipation of effort-demanding (but not in anticipation of undemanding) tasks (Tamir, 2005). The author explained these results by arguing that trait-consistent affective states have instrumental benefits for the individual in effortful situations. Individuals high in extraversion feel rewarded by social acknowledgment and praise, which can be achieved by approach behaviors. Feeling elated and happy is congruent with such an active approach orientation. Individuals high in neuroticism, in contrast, gain rewards from successfully evading threats and punishment. Feeling worried is congruent with such a disposition to avoid negative outcomes. Tamir further proposed that such trait-consistent affect leads to greater task engagement and better task performance. Supporting this idea, individuals scoring high on neuroticism were indeed faster in making valence distinctions when being in a negative as compared to a neutral mood (Tamir and Robinson, 2004), and solved more anagrams after recalling a worrisome versus happy event from their past (Tamir, 2005).

Self-Esteem

Self-esteem refers to an individual's global evaluation of, or liking for, him- or herself. In several studies, people with low self-esteem were less motivated to attenuate negative affect (Heimpel et al., 2002; Wood et al., 2009) and to maintain positive affect (Wood et al., 2003). Enhancing the salience of personal failure or social-rejection experiences further enhanced such contra-hedonic tendencies in participants with low self-esteem (Wood et al., 2009). Evidence within this research tradition further showed that people low in self-esteem felt less deserving of positive affect, and regarded negative affect as more consistent with their self-image than people high in self-esteem. According to self-verification theory, people strive to maintain consistency in their self-views, even if these are unfavorable, because stable self-views enhance the predictability of events and thus provide a sense of control. Striving for self-consistency may thus be among the mechanisms underlying the differences in affect-regulation motivation between individuals with high and low self-esteem (Wood et al., 2009).

Cultural Differences

A frequently used approach to differentiate between cultures is to categorize them as being either individualistic or collectivistic. Members of individualistic cultures tend to define themselves as being unique, to strive for independence and the assertion of their individual interests. Members of collectivistic cultures, in contrast, tend to perceive themselves as being an inseparable part of their social context, to strive for social harmony and the fulfillment of their social duties. Western cultures are typically individualistic, whereas Eastern cultures are often collectivistic.

Affective states likely differ in their instrumental value for the achievement of these culture-specific strivings, which should lead to culture-specific differences in how affective experiences are valued. For example, affect that signals successful approach to personal goals (e.g., pride) should be more important in individualistic cultures, whereas affect that signals failure to meet social obligations (e.g., guilt) should be more important in collectivistic cultures (Eid and Diener, 2001). Empirical evidence indeed suggests cultural differences in the appreciation of affective experiences. Westerners tend to regard positive affect as being more desirable, and negative affect as being more undesirable than Easterners do (Eid and Diener, 2001). Easterners, in contrast, regard finding a dialectical balance between positive and negative affective experiences more valuable than Westerners do (Miyamoto and Ma, 2011).

Similar differences have also been found with regard to the actual affective lives of members from individualistic versus collectivistic cultures. Easterners tend to experience positive affect less frequently than Westerners do (e.g., Mesquita and Karasawa, 2002). Furthermore, positive and negative affect is less negatively correlated (i.e., less mutually exclusive) among Easterners than among Westerners, suggesting a greater likelihood to experience positive and negative affect simultaneously (e.g., Perunovic et al., 2007).

Again, it seems likely that people's affect-regulation motivation is among the mechanisms that mediate these

culture-specific differences in affective experiences. Across a series of studies, Miyamoto and Ma (2011) indeed found that Westerners reported more prohedonic affect-regulation motivation than Easterners did. While Westerners had a clear preference for maximizing positive, and minimizing negative affect, Easterners were more inclined to seek a middle way to balance experiences of positive and negative affect.

Summary and Outlook for Future Research

Affect-regulation motivation refers to how people want to influence their affective experiences. In psychologically healthy individuals, it is typically prohedonic, that is, directed at the enhancement or maintenance of positive affect, or the dampening of negative affect. Occasionally, however, it can also be directed at the enhancement or maintenance of negative affect, or the dampening of positive affect. Such contra-hedonic motivation is accompanied by momentary impairments in the individual's cognitive capacity, which is likely due to the effort that is needed to overcome the prevailing prohedonic orientation.

Two theoretical explanations for occurrences of contra-hedonic motivations have been discussed. The mixed-affect perspective proposes that people occasionally seek negative affective experiences because they are accompanied or followed by positive affect. The instrumental-affect perspective maintains that contra-hedonic motivation may arise when negative affect is helpful for, or positive affect detrimental to the individual's goals. Empirical evidence supports both positions, suggesting that they are complimentary rather than mutually exclusive explanations of contra-hedonic motivation.

Affective experiences vary substantially between individuals. Such differences have been associated, for example, with people's age, their personality, and cultural background. The mechanisms underlying these individual differences in affective experiences are not yet fully understood. Evidence suggests, however, that people's affect-regulation motivations may be one of them. In part, the affective differences between individuals from different age groups or cultural backgrounds, or between individuals with different personality dispositions thus appear to be sought and maintained by the individual actively (although not necessarily consciously). Within the age range from adolescence to old age, for example, contra-hedonic motivation is most prevalent in adolescence, whereas prohedonic motivation is most pronounced among older adults. Furthermore, neuroticism and low self-esteem are associated with less prohedonic and more contra-hedonic motivation, whereas the reverse association pattern has been observed for extraversion. Differences in affect-regulation motivation have also been observed between cultural contexts. Prohedonic motivation, for example, is more pronounced among members of Western, individualistic cultures. Members from Eastern, collectivistic cultures, in contrast, tend to be more inclined to seek a dialectic balance of positive and negative affect.

Among the most important research desiderata in this field of study is the rigorous investigation of the sequence of causality in the observed associations, using appropriate experimental and longitudinal study designs. This will provide a sound empirical basis for distinguishing between antecedents and consequences of different types of affect-regulation motivations. A particularly relevant question in this regard pertains to the link between an individual's affect-regulation motivation and his or her actual engagement in, and success of, affect-regulatory behaviors. The motivation-behavior gap is a well-known phenomenon of human volition, and likely also applies to the specific case of affect-regulation motivation. Having a particular goal does not imply that the individual necessarily engages in its active pursuit, nor does it guarantee that he or she will eventually attain it. An interesting task for future research will therefore be to identify factors that determine whether and how successfully individuals implement their affect-regulation motivation in actual regulation efforts. A related question refers to the longer-term adaptiveness of different types of affect-regulation motivation (cf Tamir and Ford, 2012b). Do certain types of affect-regulation motivation play a role for the individual's longer-term socioemotional adaptation? For example, does contra-hedonic motivation really facilitate the socioemotional adaptation of adolescents, as has been speculated in the literature (Riediger et al., 2009)?

Meticulous investigation of many of these questions would require longitudinal study designs. Such designs would also make it possible to address another important issue regarding the observed age differences in people's affect-regulation motivation: They could help to determine the extent to which these age effects result from differences between birth cohorts rather than from developmental changes within persons growing older.

Affect-regulation motivation has typically been conceived of as a phenomenon that can either be deliberate and intentional or proceed automatically and without conscious awareness. An interesting task for future investigations will be to unravel these different forms of affect-regulation motivation, and to investigate possible consequences that congruence or divergence between deliberate and automatic affect-regulation motivation may have. A related open question refers to the modifiability of affect-regulation motivation. Can individuals, perhaps with the help of an outside intervention, change the way they want to regulate their affective experiences?

Last but not least, types of affect-regulation motivation so far have been primarily distinguished with respect to the valence (i.e., the pleasantness/unpleasantness) of the affective experiences that an individual seeks to regulate. An interesting task for future investigations will be to consider the role of the to-be-regulated affective experience's other characteristics as well; such as its arousal level, or whether it is a relatively short-lived, specific emotion, or a relatively more unspecific and longer-lasting mood.

Taken together, the research reviewed in this article has demonstrated that the systematic empirical inquiry of affect-regulation motivation is a promising tool to further the understanding of affective experiences in general, and of individual differences and within-person fluctuations therein in particular. Many questions, however, still remain to be investigated in the future.

Affirmative Action: Comparative Policies and Controversies

Christopher McCrudden, Oxford, UK

This article is a revision of the previous edition article by C.D. Cunningham, volume 1, pp. 210–214, © 2001, Elsevier Ltd.

Abstract

Affirmative action includes measures attempting to increase the participation of particular groups in those contexts in which those groups are regarded as underrepresented. Equivalent policies operate in several other countries in ways that have sometimes borrowed from the United States but mostly taken diverging paths. An overview of the ways in which different jurisdictions approach the issues of affirmative action is provided. A taxonomy of affirmative action measures is developed focusing on five main elements of such policies; six primary justifications for affirmative action are identified; the problems of defining preferred groups are considered; the main areas of political and economic life in which affirmative action tends to be used are described; and the major legal constraints on introducing and continuing affirmative action measures are discussed.

Introduction

The term 'affirmative action' originated in the United States, where it has been both legally and politically controversial at least since the late 1960s. 'Affirmative action' includes measures attempting to increase the participation of particular groups defined in status terms (such as race or gender) in those contexts in which those groups are regarded as underrepresented. Equivalent policies operate in several other countries in ways that have sometimes borrowed from the United States but mostly taken diverging paths (see McCrudden, 2011). Although there has been extensive descriptive and legal analysis of these measures in individual countries, comparisons among a small number of countries (Weisskopf, 2004; Lieberman, 2005; Nesiah, 2000), and several overviews of a range of many countries (Jain et al., 2003; Weiner, 1983; Tomei, 2005; Sabbagh, 2004a; Faundez, 1994), there have been few attempts (Tushnet, 2004; Sabbagh, 2004b; Cunningham, 2002) rigorously to assess such measures comparatively and in a cross-disciplinary perspective.

'Affirmative Action' and Cognate Terms

An initial difficulty in the comparative study of the issues involved with affirmative action thus defined is that different countries have different ways of describing this phenomenon. Some countries use the term 'affirmative action,' borrowing from the US usage, as is the case in Fiji (Cottrell and Ghai, 2007) and Northern Ireland (McCrudden, 1992). 'Positive action' is the term most often adopted to describe these types of measures in Great Britain (Welsh et al., 1994), as well as in the context of European Union law and policy (De Vos, 2007). Other countries and regions tend to use other terms either as well as or instead of the term 'affirmative action,' such as '*parité*' in France (Bird, 2001), 'quotas' in Brazil (Htun, 2004), 'employment equity' in Canada (Abella, 1984) and South Africa (Thomas, 2002), 'reservations' in India (Hooda, 2001), 'preferential policies' or 'special rights' in Malaysia (Haque, 2003), and 'black empowerment' in South Africa (Tangri and Southall, 2008). International human rights law tends to use the term 'special measures' (Bossuyt, 2002). Nevertheless, despite these (and other) important differences, these jurisdictions would generally be viewed as exemplars of the major varieties of affirmative action in the contemporary world.

Those countries that refer to their measures as 'affirmative action' often wish to associate their practices with those of the United States, as was the case in Northern Ireland, South Africa, and Fiji, where the US precedent was regarded as politically significant. In contrast, other countries that have developed their measures since the American debate became so dominant transnationally adopted other terminology, often consciously in order to contrast what that jurisdiction thought it was doing with what it thought affirmative action meant in the United States. One example is Canada, which developed the concept of 'employment equity' partly in order to distance what Canada was doing from the US debate (Abella, 1984). Another is France, where the term 'affirmative active' is often used to distinguish from and contrast with what is regarded as acceptable in the French context (Sabbagh, 2002). In Northern Ireland, some policy makers during the 1980s (largely unsuccessfully) sought to borrow the Canadian terminology of 'employment equity' in order to distance what they proposed from the American concept (Osborne, 1991).

Types of Affirmative Action Measures

The term 'affirmative action' is an 'umbrella' concept, under which many different types of programs shelter. There are five broad categories of measures: positive measures to avoid unlawful discrimination; indirectly inclusionary measures; attracting qualified candidates using advertising and training targeting the underrepresented group; 'tie-break' policies, where individuals from underrepresented group are preferred where equally well qualified; and preferential treatment for members of the targeted group.

Positive Measures to Avoid Unlawful Discrimination

There are three types of positive measures taken to avoid unlawful discrimination that are sometimes classified under

affirmative action: (1) activity preventing and remedying direct discrimination; (2) activity taken proactively to remove indirect, systemic, and institutional discrimination; and (3) reasonable accommodation measures, taken to enable an individual from a particular group to gain access to particular employment or a particular service, for example, changing physical aspects of the work environment to accommodate a person who is physically disabled. The South African Employment Equity Act 1998, section 15, specifies that the types of affirmative action contemplated include 'measures to identify and eliminate employment barriers, including unfair discrimination, which adversely affect people from designated groups,' and 'making reasonable accommodation for people from designated groups.' It is controversial whether reasonable accommodation measures should be regarded as a form of affirmative action, and in the United States, for example, they would be unlikely to be classified as such. These three activities amount to little more than adopting positive measures to avoid what is generally unlawful discrimination, for example, where the employer agrees to remove symbols from the workplace that may well constitute unlawful harassment against a particular group if they remained, or where the system of 'last in, first out' as the basis for making redundancy decisions is replaced by a system with less adverse effects on newly hired minorities, or where an equality body engages in a campaign to urge employers not to discriminate, or where an employer is required to make reasonable efforts to accommodate persons with disabilities, as in the Namibian Affirmative Action (Employment) Act 1998, section 17. More controversially, other measures are sometimes adopted in this context to enable discrimination to be more easily proven, or disadvantage to be more easily identified, such as the collection of statistics by way of monitoring the participation of the targeted group in particular economic activities.

Indirectly Inclusionary Measures

This includes measures such as government assistance targeted at particular inner city areas, for example, resulting in some racial or ethnic groups benefiting disproportionately because they are disproportionately represented in these areas. In the United States, there was much discussion during the 1990s as to the possibility of replacing 'affirmative action' measures that explicitly took race into account, with indirectly inclusionary measures. For example, following the decision of a US Court of Appeals for the Federal Circuit to prohibit race-based affirmative action in student admissions at the University of Texas (*Hopwood v. Texas*, 1996, overturned in *Grutter v. Bolinger*, 2003), the University adopted a system of guaranteeing admission to those students in the top 10% of their class in each High School in the state. Given the highly segregated nature of much of the school system in Texas, this had the effect of producing a significant number of black and Hispanic students eligible for admission to the University. The Fijian Social Justice Act 2001 provides a set of other examples, including the provision of grants targeted at schools with poor academic achievement, and access to training for rural youth. In the Northern Ireland context, a social program devised by government in the early 1990s, termed Targeting Social Need, began as an assistance program targeting geographic areas where need was greatest, with the understanding that this was done in order to reduce the economic disparities between Catholics and Protestants (Hinds and O'Kelly, 2006). These measures sometimes serve as an alternative to other (unacceptable) types of affirmative action.

Advertising and Training Targeting the Underrepresented Group

The third group of affirmative action measures include 'outreach' programs and have traditionally been popular across the political spectrum in several countries (European Commission, 2009). These programs are designed to attract qualified candidates from the previously underrepresented group in two ways: first, by bringing employment opportunities to their attention and encouraging them to apply for permanent employment; and second, by providing training to better equip them for competing on equal terms when they do apply for such employment. These types of measures are sometimes said to operate on the 'supply side' of the equation, meaning that they are intended to affect the behavior of the underrepresented group, rather than on the 'demand side,' referring to measures intended to affect the behavior of employers.

Tie-Break Policies

Tie-break policies operate on the 'demand' side and are more controversial, involving a preference for the person from the underrepresented group, but only where two or more individuals are otherwise equally well qualified. They involve the direct identification of individuals from the targeted group as beneficiaries of the policy, but they have no clear impact on traditional conceptions of 'merit' since traditional conceptions of merit are neither changed nor challenged. Although controversial, they are among the more common types of affirmative action in practice, and have been described by Buchanan (1989) as a 'paradigm of affirmative action.' The US Supreme Court upheld tie-break affirmative action in the context of gender under federal employment discrimination law (*Johnson v. Transportation Agency, Santa Clara County*, 1987). The European Court of Justice held that such tie-break measures operating in favor of women in some of the German *Länder* could be lawful under European Community law (*Marschall v. Land Nordrhein-Westfalen*, 1997). In Britain, the Equality Act 2010 has introduced provisions permitting the use of a tie-break in certain circumstances.

Preferential Treatment for Members of the Targeted Group

Preferential treatment is the classic affirmative action measure and the type of affirmative action measure that is probably most associated in the public mind with American-style affirmative action. These are the affirmative action measures that elicit the most heated debate because they involve the possibility that a less 'well-qualified' person from the underrepresented group would receive the benefit at the expense of the better 'qualified' person. There are, however, important differences between the different types of programs that come under

this broad heading, relating to the type of preference accorded, and the situation in which the preference is accorded. For example, a preference for a particular candidate from the underrepresented group where the preferred candidate is less well qualified, can be distinguished from a general quota in favor of candidates from the underrepresented group. The Fijian Social Justice Act 2001 provides numerous examples, including preferred equity funding for Fijians and Rotumans, educational scholarships designed exclusively for Fijians and Rotumans, provision of special funding to Fijians and Rotumans to buy houses, government assistance only to Fijians and Rotumans to acquire and develop farm land, and quotas for Fijian- and Rotuman-owned businesses to be awarded government contracts.

These methods are usually seen as limiting the operation of 'merit,' but an important variation on this approach involves redefining merit, for example, changing the traditional criteria for admission to university or employment in such a way that the new criteria are more likely to favor candidates from the underrepresented group. Both these types of affirmative action are seen as posing the greatest challenges for traditional conceptions of 'merit' in the sense that in the first traditional 'merit' is overridden in favor of increasing participation, and in the second 'merit' is redefined to include characteristics that the targeted group are more likely to have. For example, a policy may be introduced (as it was in Northern Ireland) requiring a proportion of candidates for the police force to be from a particular ethnic group in order to ensure that policing is acceptable to that group (McCrudden et al., 2004). Another example is provided in the provisions of the Hesse law upheld by the European Court of Justice in *Badeck v. Hessischer Ministerpräsident*, 2000 in which family work and care responsibilities at home were included in a list of suitable qualifications for employment in the public sector, favoring women.

Aims and Justifications for Affirmative Action

The circumstances leading to the introduction of affirmative action in a particular country often have distinct implications for the subsequent development of affirmative action in that jurisdiction. In the European Union, affirmative action began in the context of gender equality, and is voluntary, and has now expanded to include provisions permitting affirmative action in the context of other groups (De Vos, 2007). In India, affirmative action began in the context of caste and is compulsory in the public service, and has now expanded to encompass gender (Nesiah, 2000). Affirmative action that arises from tensions that have contributed to major public order problems, such as Malaysia, will likely take different forms (Haque, 2003). There are also important differences in terms of the size of the target group to benefit, compared to other groups in the country, with consequential effects on the political salience of the issue.

Several different types of justifications are put forward in different jurisdictions, depending in part on the historical context in which affirmative action first developed. At least six separate justifications may be identified that are analytically distinct, although any one jurisdiction may draw on two or more in combination.

Helping to Prevent Current Direct Discrimination and Addressing Stereotyping

This justification is particularly associated with the approach adopted in some of the cases decided by the European Court of Justice regarding positive action for women. The Court adopted an argument that positive action may be justified as a way of addressing stereotyping of women and the resultant segregation of women in particular occupations (see, for example, *Badeck v. Hessischer Ministerpräsident*, 2000).

Compensation for Past Discrimination

Originally, this was probably the most widely used justification for affirmative action in the United States, where affirmative action was often seen as compensation for decades of segregation following centuries of slavery. In the United States, this rationale had two variants: where the past discrimination was carried out by the institution or employer who now is required or wishes to engage in compensatory affirmative action; and where the past discrimination is societal and the particular employer was not directly responsible for this discrimination in the past. The former remains an acceptable basis for limited types of preferential treatment; the latter has long since been held by the US Supreme Court to be an unacceptable basis for preferential treatment (*Regents of the University of California v. Bakke*, 1978).

Egalitarian/Redistributive Argument

Edwards (1995) has identified affirmative action as "one means of effecting some redistribution of resources to minority groups in order to improve their general standing in society and their quality of life and, in the process, of enhancing distributive justice." This is the rationale that is frequently articulated in the decisions of the Indian Supreme Court addressing affirmative action in the context of caste inequalities, as well as remedying past discrimination, to justify affirmative action for *dalits* (*Indra Sawhney v. Union of India*, 1993). Whether or not this rationale is explicitly identified as a basis for affirmative action will often depend on how far this type of affirmative action is seen as contributing to or going against the grain of other aspects of the country's social policies.

Identity and Recognition

Under this justification, affirmative action is advocated, according to Cottrell and Ghai (2007: p. 229), "to maintain the cultural values and institutions of community." They continue: "Affirmative action takes the form of special representation in state institutions, protection from cultural practices even if they may be inconsistent with general national norms, control over land, and forms of self-government." In this context, affirmative action 'positively promotes the value of group identity.' Thus, this type of justification is most commonly used when affirmative action is used in the context of aboriginal peoples.

Diversity Argument

Diversity-based rationales seek to justify affirmative action on the grounds that achieving a greater mix in the composition of

schools, universities, police forces, and employment is good for society and for the organization engaging in affirmative action. Diversity in the classroom is said to improve the educational experience because students' understandings of the world are challenged by exposure to a broader range of perspectives. More diverse organizations are said to make better decisions, because managers are likely to consider a wider variety of possibilities. Organizations that serve a diverse customer base are said to better serve their customers by having a more diverse workforce. The diversity argument is sometimes made as justification for affirmative action in US higher education and has been accepted by the US Supreme Court as constitutional in that context (*Gratz v. Bollinger*, 2003; *Grutter v. Bollinger*, 2003). It has also been applied in other jurisdictions, such as France (Bird, 2001; Sabbagh, 2002). Diversity has also been embraced by human resource managers in several jurisdictions, such as Britain, as the appropriate basis on which to manage personnel (Albrecht, 2001).

Social Cohesion Argument

In some societies where group differences have contributed to such significant divisions that physical conflict has resulted, affirmative action has sometimes been put forward as part of a package of measures aimed at promoting social cohesion and ensuring greater social harmony (Faundez, 1994).

Combinations

In practice, most jurisdictions tend to combine reasons for introducing affirmative action measures, and justifications may well change over time. Occasionally, multiple and changing justifications become problematic within a jurisdiction.

For example, in Northern Ireland, affirmative action began in the context of the public order problems associated with political and economic differences between Catholic Nationalists and Protestant Unionists. Allegations of employment discrimination against Catholics was rife, indeed dating back to the foundation of the state in 1920. Not surprisingly, then, rationales based on past and current discrimination have been the most commonly articulated as justifications for affirmative action directed at advancing the economic position of Catholics. However, such social justice rationales cannot underly the affirmative action provisions in fair employment legislation and practice, which are symmetrical and require Protestant underrepresentation in firms to be addressed as well.

Articulating the justification behind affirmative action for Protestants in Northern Ireland requires another explanation, which may be either pragmatic or principled. The pragmatic reason appears to be that the politics of Northern Ireland is such that if affirmative action were to have been presented simply as a zero-sum game, in which Protestants lost out 'their share' of employment, there might well have been such resistance that it would not have been implemented at all, and thus in order to safeguard against this possibility, Protestants were included as well. A more principled explanation is based on the recognition of identities, that it was seen as important for Protestants to feel that they continued to be an important part of Northern Ireland society, and this meant that they too should be represented across political and economic institutions. Northern Ireland, like Fiji, may therefore be an interesting example of the interaction of these different rationales. If that is the case, then the Northern Ireland example may be a useful test case of a long running controversy between those who see recognition rationales and social justice rationales as mutually antagonistic (Fraser, 2000), and those who see them as mutually supportive (Young, 1997).

How Is the 'Preferred' Group Defined?

Which Groups

The issue of which group (or groups) is defined as the beneficiary of the affirmative action program is another crucial variable. Several jurisdictions have constructed affirmative action programs to benefit women. Where affirmative action is adopted for one group, it is also common for it to be used to benefit other status groups that are disadvantaged in some particular respect, usually economically. Where the 'preferred groups' are women and other groups such as disabled workers, the justifications for affirmative action may be different from those justifying affirmative action in favor of minority racial groups. Differences are also likely to arise between jurisdictions where the beneficiary is part of a 'minority' (as in the United States and Canada; in Canada, the term used is 'visible minorities'), and jurisdictions where the affirmative action is applied to benefit (part of) the majority community (as in Malaysia and South Africa). The proportion of the population that may stand to benefit from preferences, therefore, differs markedly from country to country. Affirmative action may therefore be used to benefit the majority or the minority, and the political and economic cost analysis may vary accordingly.

Aboriginal Groups

Although women, disabled persons, and ethnic minorities have tended to be the groups most likely to have affirmative action measures applied to them, a complicated relationship has emerged between affirmative action measures and aboriginal groups. Here is also where the terminology of 'affirmative action' takes on a strongly political connotation. To term measures that particularly protect aboriginal peoples as 'affirmative action' seems to imply that these groups are in some sense equivalent to women, disabled persons, or ethnic minorities, but many aboriginal peoples resist that equivalence, regarding their moral (and in some cases legal) claims as based on their position as having been in occupation of territory long before the now-dominant group arrived. From this point of view, the rationale for measures protecting these groups differs significantly from the rationales for affirmative action discussed earlier. In the aboriginal context, the rationale for protection is based on the moral or legal claims of original occupation. Special protection measures for aboriginal peoples differ not only in their rationale, but also in the type of measures adopted. Thus, as in Canada and the United States, there is a greater likelihood that such measures involve the transfer of land to the aboriginal group over which the group exercises some degree of 'sovereignty.' Despite these differences, the term 'affirmative action' has been used in some jurisdictions to describe these measures, notably in Canada. In

other countries, too, the measures adopted bear a striking resemblance to those that are termed 'affirmative action.' So, for example, in Taiwan there are provisions establishing preferences for aboriginals in education, procurement, and representation in the legislature.

Symmetrical and Asymmetrical Affirmative Action

Thus far, we have assumed that affirmative action programs are asymmetrical in their targeting of the beneficiary group, and this is indeed the case in many of the jurisdictions that engage in affirmative action. Women (but not men) benefit in the United States, as do black (but not white) Americans, as do native (but not non-native) Malays in Malaysia. In the case of affirmative action used to address disadvantages associated with physical or mental disability, it is usually the case that disabled (not able-bodied) persons benefit from such action. That is not the case in several jurisdictions, however, where the way in which affirmative action is defined means that, at least theoretically, affirmative action could be applied symmetrically. Thus, in Britain, the Equality Act 2010 permits affirmative action to be undertaken not only to benefit women but also men, and black British but also white British. In practice, however, although defined in such a way as to be theoretically symmetrical, in practice these measures are usually *applied* asymmetrically. A unique feature of the Northern Ireland affirmative action program, however, is that it has not only been defined symmetrically to address inequality between communities defined in terms of religion, it has also been applied to target both the majority and the minority communities where there is significant underrepresentation of either group employed in particular firms (McCrudden et al., 2010).

Determining Membership of the Targeted Group

To the extent, as is likely, that the beneficiaries are defined in 'group' terms, the further question is how membership in the group is to be determined. Who is to be regarded, for example, as a member of a 'racial' or 'ethnic' group for affirmative action purposes? This has proven particularly problematic in some contexts. In Brazil, the problem has been that whilst affirmative action has been applied to benefit those who are 'black,' the use of color to designate the beneficiaries has proven difficult in a society where there is every shade along a spectrum from 'white' to 'black' (Racusen, 2004). In India, the issue of who should be regarded as a member of a particular caste has arisen (Jenkins, 2009; Galanter, 1984). In South Africa, the High Court has held that a person who is of South African Chinese origin should be defined as 'black' for the purposes of benefiting from 'black empowerment' measures (*Chinese Association of South Africa v. Minister of Labour*, 2008). In other words, the problem is how to go about identifying individual members of the group once that group is defined as the beneficiary.

Crudely, two methods have been adopted. One method involves 'self-identification' in which an individual claims to be a member of the benefitted group and that claim is accepted by those operating the program. Alternatively, a system may be adopted in which membership of the group is determined 'objectively' either by some authority associated with the group (with the possibility that this reinforces the existing power structures within the community) or by a state authority such as the judiciary (with the possibility that this leads to 'essentialization,' where designated characteristics come to be considered as fixed traits, and variation among group members is discounted or ignored).

The 'Creamy Layer' Issue

In some countries, there is an attempt to ensure that affirmative action is targeted only to that part of the status group that suffers the greatest economic deprivation. In India, for example, one of the benefitted groups (the so-called backward classes) is defined so that those who are economically at the top of a backward class (the 'creamy layer,' as it is called) are excluded from preferences (*Indra Sawhney*, 1993). In these contexts, the relationship envisaged between the group and the individual members of the group becomes quite complicated, and to some extent the application of affirmative action needs to be justified at the level of the individuals. In other jurisdictions, this does not seem to be important (Malaysia, United States).

Who Loses Out?

Another way of viewing the question of beneficiaries is to contrast them with those who may lose out as a result of affirmative action policies, but here too the issue is likely to be complicated. There is likely to be significant debate if there are in fact any losers, who they are, and what the nature of any loss is, particularly when set against the benefits. Those who see themselves as 'losers' may differ from those who are perceived by others as losers, and may differ also from those who may actually lose out in practice. The issue of who loses and how much may well also affect the extent and duration of affirmative action programs. Thus, for example, in the United States, there has been greater unease in affirmative action applying to areas such as layoffs and redundancy, leading to modifications of last-in first-out, for example, in part because those who would lose out are likely to be more identifiable and stand to lose what they regarded as their legitimate expectations as to how they would be treated. The importance of identifying the potential losers is also to identify where the potential resistance to affirmative action may come from, and the nature of that resistance: the application of affirmative action in different sectors is likely to lead to different sets of losers, with differing capacities and opportunities to resist.

In Which Sector Is Affirmative Action Adopted?

Employment

There are different aspects of the employment relationship in which affirmative action may be used, with some programs involving affirmative action measures in the pre-employment stage, with efforts being placed on encouraging individuals from underrepresented groups to apply to firms that they might not previously have applied to, or training individuals in groups that are thought to lack certain skills to enable them to apply successfully for employment.

Affirmative action measures may also extend to hiring, while others extend to promotion and layoffs as well.

There is also an important issue as to whether the employment covered is public only or whether it also extends into the private sector. In several countries, affirmative action in employment extends only to the public sector, since that sector is seen as appropriately reflecting the make-up of the population as a whole. In countries such as India, where employment in the public sector has been a significant proportion of the employment market as a whole, the move to privatization has occasioned considerable debate as to whether affirmative action should begin to apply in private sector employment.

Political Representation

One of the fastest growing affirmative action measures is in the area of political representation, particularly as regards the role of women. In most countries, women are underrepresented in the political life of their country, and there is an increasing move to address this by introducing affirmative action measures of various types. One of the best known is the French *parité* system, in which there is a requirement that the lists of candidates presented to the electorate by political parties must contain a proportion of women (Stetson, 2001; Mazur, 2001), but similar systems have existed in many other countries for some time (Caul, 2001; Matland, 1998). Sometimes, as in the United Kingdom, political parties have been permitted to set up a system to ensure that the shortlist for selection as the Party's candidate for a parliamentary election includes at least one woman (Sim, 2000). In other countries, such as India with regard to the Scheduled Tribes and the Scheduled Castes, representation in the legislature is guaranteed to particular groups.

Education

Affirmative action may be used both at the level of primary and secondary education, and at the level of tertiary education, as in the United States (Bowen and Bok, 1998), Brazil (Htun, 2004), India (Nesiah, 2000), and Fiji (Puamau, 2001). The measures adopted may range from setting aside a set proportion of places for the preferred group in each year's incoming class, or modifying the entry requirements that have to be met to reflect the life experiences of the underrepresented group, or adopting entry requirements that are formulated neutrally (such as being in the top 10% of one's high school class in Texas) but have the effect of including significant numbers of the underrepresented group. A somewhat different method, which is usually not called 'affirmative action,' is to permit the establishment of schools catering specifically for a particular group defined in religio-ethnic, or gender, terms.

Public Procurement Contracts

Several countries, for example, Canada, the United States, Malaysia, and South Africa (McCrudden, 2007), adopt affirmative action preferences for those bidding for public contracts, in the form of preferences for businesses owned or controlled by members of the preferred group. Given that in many countries the expenditure by government on contracting amounts to a significant slice of GDP, this means that the impact of such preferences on the economy may be significant. The use of public procurement in this way needs to be distinguished from another common use of public procurement, which is to use access to public procurement as a method of ensuring the adoption of affirmative action in, for example, employment practices.

Control of Corporations

Several countries attempt to secure more equal distribution of economic wealth by requiring corporations to cede some degree of control to the disadvantaged group (McCrudden, 2007). South Africa, for example, has structured its black empowerment policies to ensure the transfer of corporate ownership to the black population; Malaysia has attempted to ensure that native Malays are represented on the boards of newly privatized companies. Other jurisdictions have sought to use affirmative action to increase the proportion of women on company boards. In Norway, certain public limited liability companies were required to meet gender representation requirements (Tobler, 2007). Israeli law has placed emphasis on both genders being represented on boards of state-owned companies (Izraeli, 2003).

Land and Minerals

Several countries in which the ownership of agricultural land is central to economic power and influence have introduced or contemplated introducing affirmative action measures in an effort to redistribute land from one ethnic group (often the group associated with the former colonial power) to another (often one or more of the groups associated with the move to decolonialization). This has proven particularly controversial in Zimbabwe, where extensive measures have been adopted. In Fiji, the government provides special funding to Fijians and Rotumans to acquire and develop farmland. South Africa has also envisaged the use of affirmative action measures as a tool in land reform but has not, so far at least, activated these measures. South Africa has, however, been at the forefront of using affirmative action as a method of bringing about a radical transformation of mineral development, one that sought to benefit 'historically disadvantaged persons.'

Interactions between Measures

In understanding the potential effect of affirmative action measures taken in these areas, it is important not to underestimate the extent to which there are likely to be interactions between measures taken in different areas. To take an obvious example, affirmative action taken in the area of education would be likely to affect the skills that candidates for employment are likely to be able to present and therefore the likelihood that they will be employed, which may reduce the need for affirmative action at the stage of hiring. However, affirmative action at the hiring stage may create incentives for those from previously excluded groups to undertake the education that would be useful for those jobs. Clearly, too, the greater the prevalence of affirmative action throughout the economy, the more the society will come to be dominated by group identification; the overall effect may be greater, in other words, than the sum of its parts.

Legal Constraints on Affirmative Action Measures

Legal constraints on affirmative action may arise in a constitutional document, a piece of primary or secondary legislation, a judgment from a court, or directions from a government department or other governmental body. Depending on the jurisdiction, one or more types of affirmative action may be legally or constitutionally prohibited, or legally or constitutionally permitted but not required, or legally or constitutionally required, and the difficult issue that arises is often what exactly the law does prohibit or require.

The role of law at the beginning of the process of developing affirmative action needs to be distinguished from the role of law as affirmative action develops. In the latter context, the role of law is a continuing process, and one which is often less visible to nonlegal actors. The domestic legal position is likely to be complicated by the fact that most jurisdictions will have a set of domestic legal requirements that may point in different directions on these issues, with possible tensions or conflicts between different levels of legal authority. Conflicts may arise between constitutional and legislative provisions, or between central and local provisions. One issue that has tended to recur is whether affirmative action is considered to be a permanent feature of domestic policy, or whether it is considered to be a 'temporary' remedial feature. Justice O'Connor in her US Supreme Court judgment in *Grutter v. Bollnger* (2003) viewed it as necessary that race-conscious admissions policies should be 'limited in time.' If 'temporary,' the length of time for which it is permitted needs to be specified (in *Grutter*, it appeared to be in the region of 25 years from the Supreme Court decision), as does the institution responsible for assessing that it should end.

In many jurisdictions, the relationship of affirmative action and the nondiscrimination principle has often proven to be among the most controversial legal issues, and one in which litigation is likely to take place. Here, the crucial issue is whether the affirmative action measures are seen as exceptions to the nondiscrimination principle, or regarded as a way of fulfilling the principle of equality in practice. There is a clear difference between an affirmative action program that is regarded as an exception to the general principle of nondiscrimination (as in the United States, for example), and an affirmative action program that is seen as a fulfilment of the equality principle (as in India, for example). Where affirmative action, in the form of preferences, is seen as an exception to the nondiscrimination principle, a specific exception must be crafted, if preferences are not to be subject to the nondiscrimination requirement and thus unlawful. This approach leads to a much less legally secure basis for affirmative action, although the critical question will often be the intensity of the scrutiny to which the affirmative action program is subject.

Further complications arise where, as is usually the case, a particular jurisdiction not only has domestic legal provisions that are relevant, but also has a set of international legal requirements that must be complied with. But international law does not speak with one voice on affirmative action measures, and there may be an apparent clash between international human rights law, for example, and international economic law. In some jurisdictions, therefore, there is a challenge to affirmative action authorized domestically using international human rights obligations. In other jurisdictions, domestically authorized affirmative action may be challenged using international economic law obligations arising from plurilateral trade treaties, or bilateral investment treaties (as in South Africa, see Schneiderman, 2009). As a result, one area in which there is significant difference from country to country is how much freedom there is to challenge affirmative action provisions, and where there is freedom to do so how much litigation there is in practice seeking to test the limits of permitted affirmative action and the extent of activism by the courts seeking to control the details of affirmative action programs.

Affirmative Action: Empirical Work on Its Effectiveness

Abstract

Affirmative action in the US has proceeded in the shadow of laws barring employment discrimination as well as directly under federal regulation of government contractors. Proactive steps taken by employers in response to laws (such as Title VII of the Civil Rights Act of 1964) barring employment discrimination have contributed substantially to the economic advance of blacks, but not other minorities. Affirmative action under the Contract Compliance regulations have had a more muted impact, increasing the employment share of blacks by less than 1% per year. The impact on females and on non-black minorities appears to have been even smaller. These modest gains have been achieved without the imposition of strict quotas and have not imposed substantial productivity losses. These positive impacts have faded in recent decades.

Introduction

Affirmative action generally refers to a set of public policies meant to redress the effects of past or present discrimination. The term connotes active measures to level the playing field for access to education, to jobs, and to government contracts. For this reason, affirmative action has long been a political lightning rod. To its critics, it is symbolic of quotas unfairly and rigidly imposed. To its proponents, it is symbolic of redressing past wrongs and of leveling the current playing field. An empirical basis for policies to counterbalance current employment discrimination can be sought in (1) continuing judicial findings of systematic employment discrimination, (2) statistical evidence of wage and employment disparities across demographic groups, and (3) audit studies of employers' hiring behavior. For reviews of this evidence, see Altonji and Blank (2000), Blau (1998), Heckman (1998), and Fix and Struyk (1993).

While a wide variety of affirmative action policies have been implemented in different countries, much of the existing research concerns experience with the affirmative action directed at expanding employment opportunities for women and minorities in the United States; those polices are therefore the focus of this article. One defining characteristic of the policy in the United States is its ambiguity. The closest the US Congress has come to explicitly requiring affirmative action in employment is in the Americans with Disabilities Act of 1990, which explicitly requires that employers make 'reasonable accommodations' to hire the disabled. This requires that employers must do more than be blind to differences between the disabled and the able; they must actively invest to overcome these differences. It is worth noting that during a period when affirmative action policies were contentiously debated in the US, a law explicitly requiring affirmative action in employment was swiftly enacted without mention of affirmative action.

Affirmative Action in the Shadow of Title VII of the Civil Rights Act of 1964

Affirmative action in the United States has been implicitly encouraged by judicial interpretation of Title VII of the Civil Rights Act of 1964 (CRA), and explicitly required, but not defined, by Executive Order 11 246 applied to federal contractors. From its inception, the CRA has embodied a tension between words that bar employment discrimination and Congressional intent to promote voluntary efforts to redress discrimination. The courts have struggled with making room for what they sometimes have seen as the intent of Congress within the language of the CRA. For example, in some cases the Supreme Court read Section 703(J)'s statement that 'Nothing in the act shall require numerical balancing' as allowing numerical balancing as a remedy. In other cases, the Court held that the act should not be read to bar voluntary acts to end discrimination. These cases have left considerable, if ambiguous, room for affirmative action. Furthermore, the threat of costly disparate impact litigation under Title VII (following the *Griggs v. Duke Power* case) created considerable incentive for companies to undertake affirmative action. A number of researchers have found that employers responded to the expanding role of Title VII by instituting affirmative action offices, internal labor markets, and due process procedures (Edelman, 1992; Dobbin et al., 1993).

The extent of 'voluntary' (or at least nonjudicially directed) affirmative action taken in response to Title VII can be roughly estimated from existing work on the overall impact of Title VII. Because firms directly subjected to litigation under Title VII represent such a small share of employment, the bulk of the black economic advance credited to Title VII must be due to the statute's indirect effect in promoting 'voluntary' affirmative action. For example, Freeman (1973) shows the overall impact of Title VII in the time series of black–white earnings differentials. From this, the direct impact of Title VII litigation at companies sued for racial discrimination could be subtracted. While these impacts are substantial at the companies incurring litigation, employment at such companies makes up only a small fraction of employment. The impact on market wages from the outward shift in the demand curve for blacks at these companies can only be small given their small share of the market. Most charges of discrimination never result in litigation, and much litigation never reaches a judicial decision, leaving ambiguous interpretation and little trail. It is likely that the bulk of the changes attributed to Title VII are in a broad sense the result of affirmative action taken in response to the indirect threat, rather than the direct act, of litigation. Since the impact of Title VII is at least an order of magnitude greater than

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86003-1

that of the contract compliance program, and only a small share of this could have occurred at companies directly litigated against, the biggest impact of affirmative action, broadly defined, very likely took place in the shadow of Title VII.

One difficulty in evaluating the impact of a national law such as the 1964 CRA is that there is rarely a contemporaneous group unaffected by the law that can be used for comparison. In the case of Title VII, Chay (1998) overcomes this problem by examining the impact of the Equal Employment Act of 1972, which extended the reach of Title VII to smaller establishments. Chay finds that once smaller establishments came under Title VII's coverage, the relative employment and pay of blacks improved at these small establishments. Examining changes in establishment demographics over a longer period, Carrington et al. (2000) find that there was a rapid transition of blacks, and to a smaller extent women, into large establishments in the decade after passage of the 1964 CRA. They also find that this move to larger establishments could account for a narrowing of the racial wage gap – among men – about one-third to one-half the size of that caused by convergence in schooling attainment over the post-1964 period. Again, very little of this is the direct result of litigation, suggesting the importance of indirect pressure under Title VII and through the contract compliance program. Carrington et al. argue that the shift in black and female employment toward larger establishments is a distinctive outcome of such policies.

The motive force of Title VII behind affirmative action may well have weakened recently. In defending class claims under Title VII, divide and conquer has often been an attractive tactic. In Wal-Mart Stores, Inc., v. Betty Dukes, perhaps the most important civil rights case since Griggs, the Supreme Court in 2011 raised the bar to bringing class actions under Title VII. This invites employers to rely on decentralized personnel policies and practices to reduce the size of potential classes (along with statistical precision and potential damages) in class actions.

Affirmative Action through Contract Compliance

In the US, firms that hold federal contracts (and first-tier subcontractors) are required by Executive Order to pursue affirmative action. Because the Executive Order does not apply to all companies, it sets up a contrast that under some assumptions allows us to discern the impact of affirmative action under the contract compliance program by comparing the change in demographics at contractor firms with changes at noncontractors (firms that do not hold federal contracts). The interpretation of these comparisons would be complicated if each employer's demographics or anticipated change in demographics affected its selection or self-selection into contractor status. However, there is no evidence of this. To the contrary, initial demographics are generally not used as a prerequisite to becoming a contractor. As will be explained further below, because of peculiarities in the targeting of compliance reviews during much of the program's existence, and more recently influenced by legal challenges (see, for example, Beverly Enterprises, Inc. v. Herman, 130 F. Supp. 2d 1 (D.D.C. 2000)), firms with unusually low proportions of minorities or females were not likely to come under greater regulatory pressure. Given the regulations as implemented, there has been little reason for firms with low representation of minorities or females to avoid becoming a contractor. Since firms were not held rigidly to whatever promises they may have made to increase the employment of minorities or females, there was also no reason for firms that did not anticipate an increase in female or minority share to avoid contractor status. Given that enforcement creates a generalized pressure rather than a tight link from a firm's demographics to the targeting of enforcement, reverse causation is less of a concern. We can be more confident that the differences in changing demographics between contractor and noncontractor establishment firms are not artifacts of selection or self-selection into or out of contractor status. The research on the contract compliance program allows somewhat stronger conclusions about a weaker program because it relies not just on time-series variation but on a comparison of establishments with and without the affirmative action obligation.

Two mutually inconsistent criticisms of affirmative action have found prominent voice. The first criticism is that affirmative action goals without measurable results invite sham efforts; because these programs do not work very well, the argument goes, they should be eliminated. The second criticism is that an affirmative action 'goal' is really a polite word for a quota; in other words, affirmative action works too well, and therefore should be eliminated. Empirical research into affirmative action programs contradicts both of these criticisms. Affirmative action goals have played a statistically significant role in improving opportunities for minorities. At the same time, those goals have not resulted in quotas (Leonard, 1985b).

Federal Contract Compliance Program Regulations require that every contractor maintain an affirmative action plan consisting in part of a utilization analysis indicating areas of minority and female employment in which the employer is deficient, along with goals and timetables for good-faith efforts to correct deficiencies. To put this program in perspective, it is important to understand that, through most of its history, between 400 and 1000 investigative officers have been responsible for enforcing compliance. The ultimate sanction available to the government is debarment, in which a firm is barred from holding federal contracts. In the history of the program, there have been fewer than 60 debarments. The other sanction typically used is a back-pay award. This sanction too is used infrequently (Leonard, 1985a).

There have been a few studies of the impact of the Contractor Compliance Program (Ashenfelter and Heckman, 1976; Goldstein and Smith, 1976; Heckman and Wolpin, 1976; Smith and Welch, 1984; Leonard, 1984c; Rodgers and Spriggs, 1996). Studies of affirmative action's early years have consistently found that employment of black males increases faster at establishments that are federal contractors than at those that are not, with the possible exception of the period during which the Reagan Administration undercut enforcement. While significant, this effect has always been found to be modest in magnitude. In general, the impact on females and on non-black minorities has been less marked than that on blacks.

Between 1974 and 1980, black male and female employment shares increased significantly faster in contractor

establishments than in noncontractor establishments. These positive results are especially noteworthy, in view of the relatively small size of the agency and its limited enforcement tools. First, consider differences between contractors and noncontractors in the change in female and minority employment share without controlling for other possibly confounding variables. A summary measure, white males' mean employment share, declined by 5% among contractors compared to 3.5% among noncontractors. In other words, the contractors subject to affirmative action reduced white males' employment share by an additional 1.5% over 6 years. For other groups, the comparable difference between contractors and noncontractors in the change in employment share is 0.6% for white females, 0.3% for black females, 0.0 for other minority females, 0.3 for black males, and 0.1 for other minority males (Leonard, 1984c).

Controlling for establishment size, growth region, industry, occupational, and corporate structure, the annual growth rate of black male employment grew 0.62% faster in the contractor sector, and the annual growth rate of white males grew 0.2% slower. Contractor status shifted the demand for black males relative to white males by 0.82% per year. This is less than 1% per year, not a dramatic change, although it can accumulate over time. Studies of earlier periods by Ashenfelter and Heckman (1976) and Heckman and Wolpin (1976) generally find effects on black males of the same order of magnitude. Not surprisingly, growing establishments are better able to accommodate the regulatory pressures. Minority and female employment share increased significantly faster in growing establishments.

In addition to increasing the sheer numbers of minorities employed, the program also has had some success in helping move them up the career ladder. Affirmative action appears to increase the demand for poorly educated minority males as well as for the highly educated. Black males' share of employment increased faster in contractor establishments in every occupational group except laborers and white-collar trainees. Black females in contractor establishments increased their employment share in all occupations except technical, craft, and white-collar trainee. The positive impact of the contract program is even more marked when the position of black females is compared with that of white females (Leonard, 1984b). While some part of this improvement appears to reflect title inflation by employers upgrading detailed occupational categories with a relatively high representation of minorities or females (Smith and Welch, 1984), the occupational advance is accompanied by wage increases incompatible with pure title inflation (Leonard, 1986). The evidence does not support the contention that this is just a program for blacks with skills. To the contrary, it helps blacks across the board. Thus, affirmative action does not appear to have contributed to the economic bifurcation of the black community.

These studies have only sporadically been updated because of the difficulty of accessing administrative data. Rodgers and Spriggs (1996) find slightly larger positive contractor effects on blacks in 1992 than in 1982. Holzer and Neumark (1999) compared establishments that did and did not report using Affirmative Action in hiring using a 1992–94 cross-sectional survey of about 3000 employers in Atlanta, Boston, Detroit, and Los Angeles. They find that the white male's share of total employment was about 15–20% lower in establishments using Affirmative Action.

Stainback et al. (2005) look at the black–white difference in the distribution across occupations within establishments. They find that the black and white occupational distributions were significantly more similar to each other in contractor establishments. Comparing this pattern over time, they find that the contractor effect peaked between 1973 and 1980, becoming progressively smaller in the subsequent two decades.

In a useful combination of survey data with administrative records for 814 firms between 1971 and 2002, Kalev and Dobbin (2006) report that contractor status itself has little effect on minority or female managerial employment (and perversely hurts black females), but that both multiple compliance reviews and litigation under Title VII significantly slow white male representation in management. They separately measure the impact of having an affirmative action plan, and find that this significantly improves the managerial representation of black men and white women, while reducing that of white men. They also report that corporate diversity programs increase women's representation in management and reduce that of white men. Kalev and Dobbin find that the impact of affirmative action compliance reviews fell after the 1970s. Firms that were first reviewed in the 1970s had the largest impact, and that impact persisted into the next two decades. (Firms first reviewed in the 1970s show a 4 percentage point increase in the proportion of white women in management over the period.) In contrast, firms first reviewed in the 1980s or 1990s had smaller or insignificant impacts.

In a recent work, Kurtulus (2011) extends the analysis to the 1973–2003 period. Over these three decades, she finds black and Native-American employment shares grew faster among contractor than noncontractor firms. This result, suggesting effective affirmative action, is robust when controlling for firm size, occupational structure, and industry and firm fixed effects. However, Kurtulus also finds other patterns less suggestive of a well-functioning contract compliance program. For example, the positive impact of the contract compliance program waned over time; the relatively faster growth in minority and female employment shares at contractor relative to noncontractor firms seen in the 1970s faded in the following decades. Kurtulus also finds that, perversely, white male employment shares increased under affirmative action, those of white females fell, and affirmative action failed to increase Hispanic or Asian employment shares. Additionally, the impact of affirmative action changes within a firm as it matures; minority employment share gains are sharpest in the first 4 years after a firm becomes a federal contractor, as firms adjust to their new status. Encouragingly, Kurtulus also finds that employment gains do not dissipate after a firm ceases being a contractor. In a separate study, Kurtulus and Tomaskovic-Devey (2012) present a table showing that the share of females in middle management is significantly smaller in contractor firms, although the difference is tiny. They also find that the cumulative effect of having female top managers on the proportion of female middle managers does not differ significantly by contractor status.

A different way to judge the efficacy of affirmative action is to ask whether contractor firms are less likely to generate claims of employment discrimination for which the Equal Employment Opportunity Commission (EEOC) finds reasonable cause that discrimination occurred. Hirsh and Kornrich (2008) report that the rate of reasonable-cause findings is 32% lower for sex discrimination charges and 74% lower for race charges among federal contractors compared to noncontractors.

The employment goals to which firms agree under affirmative action are not vacuous; neither are they adhered to as strictly as quotas. Affirmative action 'goals' are often considered to be a euphemism for quotas. This appears to overstate what the regulatory authorities actually require: good-faith efforts to meet goals that are in the first instance chosen by the employer and may subsequently be negotiated with the Office of Federal Contract Compliance programs (OFCCP). Under the Contract Compliance Program, firms agree to set goals and timetables. Firms that agree to increase minority employment by 10% will, on average, increase minority employment by about 1%. Employers are not sanctioned for failing to meet their goals. A good-faith effort toward compliance in practice means that firms make it about one-tenth of the way toward the stated goal. Contractor goals do have a measurable and significant correlation with improvements in the employment of minorities and females at the reviewed establishments. At the same time, these goals are not being fulfilled with the rigidity one would expect of quotas (Leonard, 1985b).

Both the contract compliance program and Title VII have been criticized for inducing firms simply to hire a 'safe number' of minorities and women, irrespective of qualifications. According to this argument, whatever 'quota' is imposed should be the same for firms in the same industry and region. Application of such quotas would mean that firms in the same industry hiring out of the same labor market should, over time, start to look more and more like each other in terms of the percent of women and minorities. This does not generally happen, either under Title VII or as a result of affirmative action programs (Leonard, 1990).

Rather than implementing quotas, employers appear to use more sophisticated methods to implement affirmative action. Surveying employers, Holzer and Neumark (2000) found that firms engaging in affirmative action: (1) recruit more extensively by using a larger number of recruitment methods per worker hired; (2) screen more intensively, and pay less attention to characteristics such as welfare recipiency or limited work experience that usually stigmatize candidates; (3) provide more training after hiring; and (4) evaluate worker performance more carefully. Kalev and Dobbin find that while attempts to reduce managerial stereotyping through diversity training do not increase diversity, setting up affirmative action plans and making managers responsible does lead to improvements in managerial diversity. Reducing social isolation among women and minorities through networking and mentoring programs has a modest impact.

As a result, there is some evidence that the general pressures of affirmative action have succeeded in prompting employers to search more widely for new employees, but at the same time have been flexible enough not to impinge upon the economic performance of these firms. Holzer and Neumark (1999) find that although affirmative action employers tend to hire minorities with lower educational qualifications, these hires do not exhibit reduced job performance. For women hired under affirmative action, Holzer and Neumark find neither a performance nor a credential shortfall.

Future Research

Classic economic models of discrimination recognize that discrimination is not only unfair, but also inefficient. The available evidence suggests that affirmative action has helped to promote black employment, and to a lesser degree employment of females and of non-black minorities. But by themselves, these employment gains do not tell us whether affirmative action has reduced discrimination or gone beyond that point to induce reverse discrimination. Two fundamental questions remain: Has affirmative action reduced discrimination and has it helped integrate society?

Whether the employment gains associated with affirmative action and Title VII have reduced discrimination or gone beyond that to induce reverse discrimination can be addressed by asking whether industries that have come under the most pressure from Title VII or affirmative action, or industries that have increased their employment of minorities and women, have suffered in terms of productivity. The earliest paper to use this approach (of comparing relative earnings to relative wages) relied on highly aggregated data and found that minority and female employment gains under affirmative action had not reduced productivity (Leonard, 1984a). Direct testing of the impact of affirmative action on productivity finds no significant evidence of productivity decline, which implies a lack of substantial reverse discrimination. However, these results at the industry-state level are too imprecise to answer this question with great confidence.

Hellerstein et al. (1999) refine this approach of comparing wage differentials to estimated productivity differentials, and develop much more persuasive results with a detailed study of establishments. They find that pay premiums for older workers are roughly matched by productivity increases, but that the female pay penalty in the United States is generally not a reflection of lower productivity. The latter result suggests that far from imposing pervasive reverse discrimination against men, affirmative action for women has not yet succeeded in eliminating labor market discrimination. This direction of research holds great promise to move us beyond the formulaic debates over whether the wage differences that remain between groups after controlling for observable differences in qualifications and preferences are due to omitted human capital or discrimination.

A second approach to this question uses stock-market returns to ask whether investors consider Title VII litigation good for companies because it forces them to use labor more efficiently. Hersch (1991) finds a negative effect on investment returns. This might mean that investors do not believe that litigation will force the firms to become more efficient. Alternatively, investors might take the litigation as news that management is more inept than they thought. Wright et al. (1995) look at the stock market response to announcements by the US Department of Labor that a company is being recognized for having an exemplary affirmative action

program. The stock of these companies jumps immediately after the announcement. In a study of initial public offerings, Welbourne (2000) reports higher stock prices for companies with more women on their management teams.

The political question of whether affirmative action has served to unify or divide is of continuing concern. Sniderman and Piazza (1993) conduct survey-based experiments in the United States and report that just using the term affirmative action is enough to provoke more discriminatory responses.

Affirmative action-type policies in education and in government contracting have drawn increasing attention. Analysis of both education and public contracting face the challenge of measuring the impact of heterogeneous policies with substantial local variation that is difficult to pin down. For higher education, see Holzer and Neumark (2006) for a useful review. Less is known about set-aside programs at the federal, state, and local level (see Bates and Williams, 1996). Chatterji et al. (2010) find that city set-aside programs increase the rates of both black employment and black business ownership. Gains under these programs tend to quickly evaporate when set-asides are suspended (Blanchflower and Wainwright, 2005). The open questions include whether there is evidence of systematic discrimination in public or private contracting, as well as how discrimination and set-asides programs affect the profitability and growth of firms. Given the context of laws designed to limit discretion in public contracting, evidence of discrimination in contracting can be thought of as a miner's canary signaling loopholes in public contracting laws.

Other Mechanisms, Other Countries

One of the most interesting mechanisms for pursuing affirmative action can be found in the German policy to promote employment of the disabled. It is a play or pay policy. Employers face an explicit quota for employment of the disabled. The German government has drawn a bright line clearly stating minimum employment share for the disabled. However, together with this clear standard is a buy-out provision; firms that do not meet their quota, for whatever reason, pay into a special government fund. This mechanism is remarkably different from those used in the United States. First, the quota is explicit and stated in terms of numerical standards rather than abstract rights. This reduces the uncertainty, risks, delays, and costs of enforcement through the courts. There is also little opportunity to argue over the existence of a hidden quota. At the same time, the buy-out provision defuses complaints about the costly burdens imposed by rigid quotas, because employers experiencing the greatest difficulty meeting the quota can buy their way out. The nearest example of a US policy using a similar mechanism is the creation of tradable pollution rights under US environmental law. Both mechanisms are desirable on efficiency grounds. Firms that face the greatest difficulty reaching the legal standard can buy the right to pollute (or to hire fewer disabled) from firms that can more easily meet the standard. The aggregate level of disabled employment can be adjusted by changing the overall standard and/or the price, leaving to a decentralized market mechanism the question of which firms will employ the disabled and which will pay a fine. One additional benefit is that the penalty paid by firms below quota goes into a fund used to support the training and rehabilitation of the disabled.

Whatever its desirability on efficiency grounds, this mechanism appears to be politically impractical as a solution to race and sex discrimination in the United States. Explicitly setting quotas and putting a price on the right to employ fewer minorities or women raises political conflicts. The current policy places only an implicit price on discrimination. But it is apparently politically advantageous to frame the discussion in terms of absolute human rights, rather than to explicitly highlight the relative price society is willing to put on these rights through enforcement budgets and employment standards.

Abstract

The sociology of affirmative action is a strongly interdisciplinary subfield within sociology. It is concerned with understanding the causes and consequences of policies that use membership in certain social groups to determine the allocation of resources or opportunities. It is also concerned with understanding the level and sources of public support and opposition to such policies. This article summarizes developments in these areas and identifies the areas that seem most promising for future researchers.

The sociology of affirmative action is a subfield that sits at the intersection of political sociology, race and ethnic relations, work and occupations, sociology of education, historical sociology, and the sociology of gender. It is strongly interdisciplinary, and it is connected with ongoing lines of related research in economics, political science, and history. The subfield has grown robustly in recent years through the contributions of both qualitative and quantitative researchers, who have explored a range of sociologically significant and policy-relevant questions.

What Is Affirmative Action?

The term 'affirmative action' is typically used in connection with a heterogeneous set of public or private policies or programs in which a person's membership in a socially defined group is a factor that determines the allocation of resources or opportunities. The social groups that are targeted by affirmative action include, but are not limited to selected racial and ethnic minorities as well as women. How group membership is identified, is weighed, and enters into the decision-making process can vary substantially from one context or setting to another.

Affirmative action programs originated roughly half a century ago in the United States, where they took root in both the public and private sector in employment, government contracting, and higher education. The phrase 'affirmative action' first appeared in proposals for antidiscrimination legislation in the 1940s, but it was injected prominently into the discourse of civil rights with President Kennedy's issuance of Executive Order 10 925 in 1961.

Affirmative action programs have assumed many different forms and appeared in a wide range of settings over time. Among their numerous incarnations are the 'goals and timetables' for the utilization of women and minorities that federal contractors are required to write out and keep on file; court-ordered or court-approved hiring quotas that were established by municipal police and fire departments trying to resolve employment discrimination lawsuits filed under Title VII of the Civil Rights Act of 1964 (CRA); various local, state, and federal laws that 'set aside' a proportion of contracts or contracting dollars for minority-owned businesses or subcontractors; various types of recruiting, hiring, and promotion programs voluntarily instituted and operated by private companies, sometimes under the aegis of guidelines issued by the Equal Employment Opportunity Commission (EEOC); and a mixed assortment of recruiting and admission programs at colleges, universities, and K-12 schools – both public and private. The most capacious conceptions of affirmative action also include race-conscious policies in legislative districting and jury selection.

Over time, multiple rationales have been offered for the establishment and maintenance of affirmative action, including the compensatory justifications that were commonplace in the early years to the more recent idea that affirmative action is essential to the attainment of racial and ethnic diversity, which is seen as educationally valuable.

Affirmative action programs were not uncommon in the United States, despite the intense political and legal controversy that often accompanied their adoption and operation. Recent years have witnessed a retrenchment in the geographical scope and institutional prevalence of affirmative action as well as a reduction in the amount of weight that group membership is given, but a meaningful array of more circumscribed programs nevertheless remains in place today.

Since the advent of affirmative action in the United States, several other countries have adopted and adapted it in a variety of different forms and a range of different contexts; among them were Brazil, India, South Africa, and Malaysia.

The Sociology of Affirmative Action

Sociologists have shown interest in a number of research questions about affirmative action, but the literature focuses on three distinct but intertwined lines of inquiry.

What Explains the Developmental arc of affirmative Action Programs in Employment and Education?

Advent, Growth, and Persistence in Employment

The most robustly developed strand of the literature is highly historical in orientation, and it explores why affirmative action in employment was initially adopted. Alongside historians and political scientists, sociologists have been mainly concerned with accounting for developments spanning the period from Kennedy through Nixon's first term – especially the series of policies issued under Executive Order 11 246 (1965), which

called upon federal contractors to take 'affirmative action.' These policies assumed definite form in the late 1960s through executive initiatives like the Philadelphia Plan – first worked out tenuously in 1967 under Johnson and then reformulated more securely in 1969 under Nixon. Both versions of the plan required federal construction contractors to write down goals for hiring minority workers. The idea of using written goals to stimulate and gauge progress had actually itself come from a group of large, private companies organized in 1961 under Kennedy's executive order. Members of the group, known as Plans for Progress, had for several years been voluntarily developing establishment-level plans for 'achieving equal employment opportunity through affirmative action.' In 1970, Order Number 4 extended affirmative action to cover all federal contractors, requiring them to set 'goals and timetables' for the utilization of racial minorities in their workforce. And 1 year later, Revised Order Number 4 extended the same requirement to cover women.

There has also been interest in accounting for a series of court rulings that solidified the legal and constitutional foundations of affirmative action. Most of these were handed down during the Burger Court (1969–86), including the decision not to grant *certiorari* in the case of *Contractors Association of Eastern Pennsylvania vs Secretary of Labor*, 442 F.2d 159 (3d Cir. 1971), which had the effect of validating the legality of the Philadelphia Plan and affirmative action in federal contracting more generally. Other key opinions of interest include *Griggs vs Duke Power Company*, 401 US 424 (1971), which among other things held that the EEOC should be given 'great deference' from the courts in interpreting the implementation of Title VII of the CRA, eventually including the issuance of regulations concerning affirmative action; *United Steelworkers of America vs Weber*, 443 US 193 (1979), which cleared the legality of voluntary affirmative action plans put into place by private employers for the purpose of remedying racial imbalances in historically segregated job categories; and *Fullilove vs Klutznick*, 448 US 448 (1980), a plurality opinion that tenuously upheld the constitutionality of a set-aside program established by Congress.

The initial origins of affirmative action were once relatively murky, but several generations of research have done much to illuminate them. A total consensus is far from evident, but there has been a loose convergence of evidence-based perspectives that differ mainly in their points of interpretation and emphasis.

One of the most developed lines of research highlights the significance of pressure from below. There is indeed solid evidence showing that affirmative action emerged in substantial measure as a response to grassroots protests mobilized by northern civil rights activists, who had been long concerned with the slow pace and meager scope of racial change that had been wrought in the skilled trades by liberal antidiscrimination policies such as fair employment practices (FEP) laws. The sense that something more than simple nondiscrimination and desegregation was needed percolated upward slowly from the grassroots all over the country. By 1965, President Johnson himself had seen fit to announce in a speech at Howard University that "freedom is not enough." In a language that would subsequently be taken as a rationale for affirmative action, he maintained that "it is not enough just to open the gates of opportunity. All our citizens must have the ability to walk through those gates."

A related but distinct perspective goes a step further, offering evidence consistent with the idea that affirmative action was not strictly a reactive response to outside protest but also a consequence of regulatory capture. According to this view, affirmative action was instituted at the behest of an increasingly radical civil rights lobby whose redistributive objectives and policy preferences began dominating the agendas of policy-making institutions throughout the executive and judicial branches.

Political culture and partisan politics are the focal points for a different line of research. The most influential study among them points to the crucial significance of the urban riots that shook many American cities in the late 1960s. It provides some evidence that the riots had the effect of legitimating color-conscious policies like affirmative action, making it possible for partisan actors to deploy it for political purposes – such as when President Richard M. Nixon used it to aggravate tension within the New Deal coalition, particularly between African-Americans and organized labor.

Still another line of work highlights the fragmented and decentralized character of political institutions in the United States, where policy-making authority is dispersed horizontally across the separation of powers and vertically across the ladder of federalism. This strand of the literature has adduced evidence that the structure of American political institutions presented a unique set of political opportunities that facilitated the rise of race-conscious policies, which would have faced much stronger headwinds if they had tried to go through Congress instead.

A final perspective points to the persistent failure of Congress to pass a law that would have promoted the equal treatment of individuals in the labor market through the operation of a strong administrative agency with cease-and-desist authority along the lines of the National Labor Relations Board. Liberals had campaigned for such an FEP law since the mid-1940s, but there is evidence that a coalition of business groups, conservative Republicans, and rural and suburban whites joined with southern Democrats to stand in the way of its passage. With the path through Congress block, what resulted was a regulatory vacuum that ironically encouraged the pursuit of race-conscious policies through a combination of executive and judicial action.

If the initial advent of affirmative action in employment has attracted much of the interest from sociologists, there has nevertheless been some interest in understanding the subsequent expansion of affirmative action. Special concern has been devoted to accounting for how and why various types of affirmative action came to include groups other than African-Americans, including Latinos, Asian-Americans, Native Americans, and women.

One salient approach highlights the importance of social protest and legal mobilization around Title VII of the CRA, especially in the case of women. A somewhat different approach focuses on policy elites and their perceptions. It suggests that African-Americans were originally the focus of affirmative action because the urban riots of the late 1960s led them to be seen by policy elites as societally disadvantaged and morally worthy of special treatment. Mexican-Americans,

Asian-Americans, and Native Americans were then swiftly included as beneficiaries of affirmative action because policy elites likened them to African-Americans, who were regarded as a benchmark of sorts. By contrast, it took women some struggle to achieve inclusion because they were seen by policy elites as morally worthy but categorically different than African-Americans. White ethnics were never included despite struggling for inclusion because they were seen by policy elites as morally unworthy and categorically different.

Affirmative action programs also expanded, in the sense that many companies without federal contracts also began instituting them voluntarily. This growth was fostered in large measure by personnel experts, who advised executives that taking affirmative action would convey a signal to legislators and judges that a 'good faith' effort to achieve equality was being made. Many companies heeded the advice, establishing affirmative action offices and appointing affirmative action officers over the course of the 1970s and 1980s. For instance, more than 25% of the companies in a 1986 survey reported having affirmative action officers, five times the percentage in 1972.

Sociological research on the advent and development of affirmative action in other employment-related areas is less abundant, but it touches on many of the same themes. Here too sociologists have argued for the importance of the riots, pointing to evidence supporting the claim that government programs meant to promote minority business were established during the late 1960s largely in the hope that they would stave off further rioting and restore order in American cities. Among these were the Section 8(a) programs of the Small Business Administration (SBA), wherein the SBA served as a prime contractor for the federal government and sought to promote the award of subcontracts to minority-owned businesses. A similar motive was evidently behind Nixon's issuance of Executive Order 11 458 (1969), which established the Office of Minority Business Enterprise to promote minority-business ownership. In both cases, programs initially meant to address the acute circumstances of African-Americans were quickly extended by analogy to racial minorities like Latinos and Native Americans, even though they themselves did not demand government action along such lines. The value of such programs became increasingly attractive to politically minded policy-makers over time. By 1977, there was sufficient momentum behind the idea of promoting minority business that Congress included a provision in the Public Works Employment Act requiring that 10% of certain funds spent under the law to go toward the purchase of goods or services provided by minority-owned businesses. Such programs – along with numerous state and local programs that were created in their image – would endure through the remaining years of the Burger Court before finding themselves on more treacherous legal, constitutional, and political terrain.

Advent, Growth, and Persistence in Higher Education

Sociological research on the establishment and growth of race-conscious affirmative action in higher education is less plentiful than research on employment, but it is growing.

Here too the 'riot hypothesis' has left a substantial footprint in the sociological literature. There is especially strong and granular evidence supporting the hypothesis in the case of Harvard, Yale, and Princeton, which abandoned race-neutral admission practices in their college admissions and witnessed a significant uptick in the enrollment of black students only after the Watts riot in 1965. Related studies suggest the possible significance of violence on campus – at the very least the threat of violence that accompanied student protest. Whatever the source of disruption, it is argued that disruption led school administrators to accept and even promote race-conscious policies, mainly out of the belief that they might serve as a steam valve that would relieve the pressure of discontent building from below.

But evidence supporting the 'riot hypothesis' in the case of college admissions is fairly limited for schools outside the Big Three. One recent study shows that affirmative action in college admissions was actually adopted in two waves. The 'first wave' started before Watts. At schools such as the University of California, Los Angeles, the University of Michigan, and Cornell University, school administrators of different partisan commitments began to experiment with race-conscious admission programs in the early 1960s, often in response to the nonviolent mobilization of the civil rights movement – such as the confrontation in Birmingham and the March on Washington in 1963. Many administrators were motivated by the belief that it was morally incumbent upon them to not just to do what they could to level the metaphorical playing field, but to take special steps to make up for decades of societal discrimination that had left so many African-Americans in a less-than competitive position in so many areas of American life. Indeed, there is mounting evidence to suggest that the initial emergence of affirmative action at many colleges occurred in the early 1960s and should be seen primarily as a northern 'ripple effect' of the campaign against racial inequality and Jim Crow segregation. To be sure, riots played a role during a 'second wave' of affirmative action, which occurred during the late 1960s, when institutions that were closely associated with Protestant elites were finally motivated to affirmatively incorporate race into their admissions criteria. Student protest in the wake of King's assassination also led many schools to intensify their existing affirmative action by putting a greater weight on race. But key numbers of colleges had already begun to incorporate racial considerations into their admission process long before uprisings in Watts, Detroit, or Newark began grabbing headlines.

For a variety of reasons that sociologists are continuing to explore, including the idea that college administrators were seeking to bolster the legitimacy of their own specific institutions as well as the legitimacy of the higher education system more broadly, affirmative action programs spread quickly in the late 1960s and early 1970s. There is also evidence that professional and accreditation associations played a key role in exerting pressure on the admission programs of law and medical schools.

But the programs were never without their critics, and controversy quickly moved into the open. Affirmative action became the subject of litigation in the federal courts, where a number of white plaintiffs filed lawsuits alleging that affirmative action violated Title VI of the CRA and the Equal Protection Clause of the Fourteenth Amendment. The opinion of a splintered Burger Court in *Regents of the University of California vs Bakke*, 438 US 265 (1978) settled some questions and left other questions ambiguous. The plaintiff in the case, Alan Bakke, had failed to gain admission to the medical school at

the University of California, Davis, which had for a time set aside 16 out of 100 seats for members of 'disadvantaged' groups. The court struck down such programs – and by implication racial quotas and separate tracks – but it appeared to accept the use of race as a single, 'plus factor' in a larger system of individualized, holistic admissions, pointing approvingly to the system operated by Harvard College. Moreover, it indicated that the underlying reason for instituting race-conscious affirmative action mattered. Race could not be considered as a way of compensating certain applicants for experiencing 'societal discrimination,' but it could be considered in the service of crafting a racially and ethnically diverse class – which the court accepted as having educational value for all students on campus.

Affirmative action endured at many American colleges and universities after *Bakke*, most obviously because the opinion offered administrators a viable legal and constitutional rationale for the restrained continuation of such programs – even if the rationale required further clarification and invited future litigation. But there is also some evidence from empirical research on certain large, selective public universities that a range of 'isomorphic' forces may have converged to facilitate the persistence of affirmative action, despite a political context that was growing more infelicitous. This included the 'coercive isomorphism' of *Bakke* itself, which imposed constitutional constraints on ways that universities could consider race in admissions. It may have also entailed a kind of 'normative isomorphism' in which diversity became a taken-for-granted organizational norm promoted by admission officers working in a rapidly professionalizing field. Finally, it may have included a kind of 'mimetic isomorphism' in which institutions coped with legal uncertainty in the wake of *Bakke* by copying the practices of the most prestigious or successful schools.

Partial Retrenchment in Employment and Education

Since the time that it was put into place, affirmative action has experienced varying degrees of retrenchment in employment and education, but a sociological literature on the causes of retrenchment is only beginning to develop.

It was during the Reagan–Bush era and the initial years of the Rehnquist Court (1986–2005) that affirmative action began to find itself under serious assault on multiple fronts. By then, it had completed a journey from partisan cipher to partisan touchstone, and the most vocal critics of the policy were frequently Republicans. Among those who were most aggressive in their opposition was President Ronald Reagan, who had campaigned against 'quotas, ratios, and numerical requirements.' His administration sought to limit affirmative action requirements to only the largest contractors, close the federal agency responsible for monitoring affirmative action compliance, and cease the use of goals and timetables by more than 50 cities.

Sociologists have pointed out that Reagan's opposition to affirmative action contributed in certain ways to the rise of diversity management in corporate America as well as the proliferation of the diversity rationale in higher education.

But the administration and other critics at the time did not experience much success in actually rolling back affirmative action. The most significant developments occurred at something of a distance from electoral politics, in the federal courts, where a series of decisions the Rehnquist Court signaled a deepening shift in the way that cases involving racial consideration would be decided. The first of these, *City of Richmond vs J.A. Croson Co.*, 488 US 469 (1989), involved a city set-aside program that required prime contractors to award 30% of the dollar value of their construction contracts to 'minority-business enterprises.' The court held that state and local programs that invoked racial considerations were indeed subject to the highest level of judicial review, known as strict scrutiny. This was essentially the same standard that was applied in but perhaps not fully fleshed out by *Bakke*. It required race-conscious policies to meet a two-pronged test. First, such policies had to serve a 'compelling governmental interest.' Second, they had to be 'narrowly tailored' to serve such an interest. The court was prepared to accept that racial considerations were valid remedies in the case of 'identified discrimination,' but it struck down the set-aside program in *Croson* on the grounds that the City of Richmond had "failed to identify the need for remedial action in the awarding of its public construction contracts."

After 6 years the court would hand down *Adarand Contractors Inv. vs Pena* 515 US 200 (1995), which held that federal programs taking race into account were also subject to strict scrutiny. The court in the next year declined to hear *Hopwood vs Texas* 78 F.3d 932 (5th Cir. 1996), in which a panel of judges from the Fifth Circuit struck down an affirmative action program operated by the University of Texas Law School, partly on the grounds that the attainment of diversity for educational purposes was not a 'compelling governmental interest' and therefore did not pass muster under one prong of strict scrutiny.

During the mid-1990s, critics of affirmative action began to experience success in state politics. In 1995, led by businessman Ward Connerly, an ally of Republican governor Pete Wilson, the Regents of the University of California voted to end affirmative action in university admissions, employment, and contracting. A year later, California voters passed Proposition 209 by a 54–46 margin, buoyed in substantial measure by the votes of non-Jewish, white Californians. The 'California Civil Rights Initiative,' as it was called by supporters, amended the state constitution to say that the "state shall not discriminate against, or grant preferential treatment to, any individual or group on the basis of race, sex, color, ethnicity, or national origin in the operation of public employment, public education, or public contracting." One sociologist points out that the wording of the initiative may have confused voters: An exit poll by the *Los Angeles Times* indicated that a quarter of those polled who voted for the initiative said they actually supported 'affirmative action.' Several states followed in California's footsteps in subsequent years, passing similarly worded laws, initiatives, or amendments. Among these included action by Washington State (1998), Michigan (2006) Nebraska (2008), Arizona (2010), New Hampshire (2011), and Oklahoma (2012). Florida ended affirmative action in 1999 through Governor Jeb Bush's executive order. Only twice did measures calling for the ban of affirmative action fail when put to a vote. The first time came in Houston, where the wording of the initiative favored those who wanted to preserve affirmative action. The second time came in Colorado in 2008, when Barack Obama was elected president.

Concerned about preserving the racial diversity of their undergraduate population, Texas, Florida, and California put

into place 'percentage plans' in lieu of affirmative action. These plans generally guaranteed admission to a state university for high school students who graduated at the top of their high school class – the top 10% for Texas (1997), the top 20% for Florida (1999), and the top 4% for California (1999).

But the retrenchment of race-conscious affirmative action eventually reached a limit in the federal courts. A pair of cases arising out of Michigan defined the legal and constitutional boundaries. In *Gratz vs Bollinger* 539 US 244 (2003), the Supreme Court struck down the admission program operated by the University of Michigan's College of Literature, Science, and the Arts – which automatically granted applicants from 'underrepresented' backgrounds a set number of points in the admission process. The court held that the program was not narrowly tailored and therefore ran afoul of the Equal Protection Clause. The court also found that the program violated Title VI of the CRA. But the court upheld the validity of the admission program operated by the University of Michigan's Law School in *Grutter vs Bollinger* 539 US 203 (2003). With the aim of capturing the educational benefits that it believed flowed from having a racially and ethnically diverse class, officials at the Law School considered race in a more flexible, individualized fashion, and the court found that their program was both narrowly tailored and served a compelling state interest – and therefore did not offend the Equal Protection Clause. The decision was especially notable because the court explicitly stated an expectation that in 25 years time affirmative action would no longer be necessary for the purposes of composing a racially and ethnically diverse class.

At present, legal contestation of affirmative action remains ongoing. In *Fisher vs Texas*, a panel of judges on the US Fifth Circuit Court of Appeals received the case on remand from the US Supreme Court and found the affirmative action program operated by the University of Texas constitutionally acceptable. The full Fifth Circuit declined to rehear the panel decision, but Fisher reportedly plans an appeal.

What Are the Consequences of Affirmative Action?

A second broad line of inquiry in the sociology of affirmative action investigates the effects of such policies – both their establishment and their elimination – on a range of employment and educational outcomes. This research confronts a number of challenges to credible inference, including the need to distinguish the effect of affirmative action from the effect of race-neutral policies as well as the 'nonrandom assignment' of affirmative action policies to unions, firms, and educational institutions. As a result, much of the research is suggestive – sometimes highly suggestive – but rarely if ever conclusive.

This is certainly the case with the literature on affirmative action in employment. But much of the research in multiple fields appears to consistently point in the direction of a positive effect on minority outcomes. One strand of work in economics is based on a comparison of employment outcomes at contractor versus noncontractor establishments, and it has yielded evidence that affirmative action redistributed employment over time from white males to white females and racial minorities as well as evidence of wage gains on the part of white females and racial minorities. Another strand features similar findings; it is based on metropolitan-level data on a broader slice of the labor force. The magnitude of the effect appears to be fairly modest regardless of the data source. A forthcoming paper on city contracting set-asides finds evidence that they significantly increased the business ownership rates of blacks. The impact on employment is not entirely clear and depends upon the nature of assumptions about previous trends. In sociology, one particularly strong study uses original longitudinal data on a fairly large sample of establishments over a 30-year period to estimate models of managerial diversity with both establishment- and year-fixed effects. It finds that affirmative action plans are generally associated with increases in the share of private-sector management positions held by white women, black men, and black women (in certain industries).

More disagreement exists concerning the effects of affirmative action in higher education. The most comprehensive study along these lines – based on the Mellon Foundation's College and Beyond database, which contains information on students who matriculated at 28 selective colleges at three different points in time – indicates that affirmative action has had significant benefits for black students. The authors find that the weight given to race is small, but the benefits are large and meaningful. While they find evidence of academic underperformance by black students, they point out that black students graduate from College and Beyond schools at high rates, attain graduate and professional degrees at high rates, earn high incomes, and become highly involved in civic and community affairs, especially in leadership capacities. But some researchers are highly critical of the study, and they argue that affirmative action actually harms black students because it gives such a large weight to race in the admission process that it catapults academically underprepared black students to selective schools where they find it difficult to perform well, thereby leading them to experience a range of poor academic outcomes. Affirmative action creates an academic 'mismatch' between black beneficiaries and the schools where they are admitted.

The balance of the literature goes against the 'mismatch' hypothesis. Some sociologists have found very little support for it when carefully analyzing data from such surveys as College and Beyond, High School and Beyond, the National Education Longitudinal Study, and the National Longitudinal Survey of Freshmen. Other sociologists have reached similar inferences after exploiting a 'natural experiment' generated by a quirk in the undergraduate admissions process at the University of California in 2004. Still other sociologists argue that academic costs of affirmative action for black students (mainly in terms of lower grades and class rank) are usually outweighed by the benefits of attending a more selective school. Yet certain researchers have drawn different conclusions based on their own empirical analysis. One prominent study analyzes data on law school and lawyers from several sources, including the Bar Passage Study of the Law School Admissions Council, the National Survey of Law School Performance, and the 'After the JD' survey. This line of research has attracted a vigorous response from numerous researchers across the social sciences, including sociologists. In fact, many of them teamed up to criticize it in an *amicus* brief filed on behalf of the *University of Texas* in the *Fisher* case.

What Does the Public Think of Affirmative Action?

A third broad line of inquiry in the sociology of affirmative action examines various facets of public opinion on affirmative action.

What 'affirmative action' is understood to mean can vary substantially from one person to another, and so the level of public support for affirmative action can be challenging to ascertain and characterize. How much there seems to be depend on the race of the respondent, what particular type of policy or program is referenced, and precisely how the question is worded. At the same time, public support for affirmative action does appear to have changed in certain, nontrivial ways over time.

Broadly speaking, sociologists and other researchers studying opinion polls over the last 40 years have usually found low levels of support for affirmative action when racial preferences are invoked by the wording of the question. In a series of polls taken by Gallup from the late 1970s to the early 1990s, only one in ten respondents tended to express support for affirmative action when 'preferential treatment' was explicitly juxtaposed to 'ability' and 'test scores' as the main basis for 'getting jobs and places in college.' In surveys conducted by CBS News and the *New York Times* (*NYT*) during the mid-1980s to the mid-1990s, around three in ten respondents supported affirmative action when they were asked if they believed that "preference in hiring and promotion should be given to blacks today" in situations "where there has been job discrimination against blacks in the past."

But researchers have sometimes found modest and even high levels of support for affirmative action, often when 'affirmative action' is mentioned and 'preferential treatment' is avoided. Some surveys in late 1970s and early 1980s revealed that more than two-thirds of respondents supported 'affirmative action programs' in both employment and higher education 'provided there are no rigid quotas.' Gallup reported in 1995 that nearly three-quarters (see Steeh and Krysan 1996: 134). of respondents in one poll approved of "companies making special efforts to find qualified minorities and women and encouraging them to apply for jobs." In a 2013 CBS News/*NYT* poll, half of respondents indicated that they favored "affirmative action programs for minorities in hiring, promoting, and college admissions," and Pew Research Center reported the next year that nearly two-thirds of respondents in a poll agreed that "affirmative action programs designed to increase the number of black and minority students on college campuses are a good thing."

What is clear is that racial differences in levels of support for affirmative action persist. A majority of white respondents in the General Social Survey (GSS), roughly 60%, has consistently endorsed the broad belief that the government does not have a 'special obligation to help improve' the 'living standards' of black Americans. Black attitudes continue to remain distinct from white attitudes, though there have been some shifts over time. The overwhelming majority that unequivocally supported the idea of a special obligation has shrunk to a large minority today, and a similarly sized minority of black respondents expresses ambivalence about the idea.

Even stronger racial differences are manifest in responses to questions that ask specifically about 'preferences.' The GSS began asking in 1994 whether respondents favored 'preference in hiring and promotion of blacks,' and nine out of ten whites consistently expressed opposition. A substantial minority of blacks opposed preferences in 1994, while today a small majority opposes them. These broad patterns are echoed in other data, including the National Election Survey.

One of the most exciting new lines of research in the area of public opinion and affirmative action uses experiments to explore how ideas about meritocracy – something critically linked to the issue of affirmative action – are not fixed but malleable. For instance, one recent lab experiment shows that white students lower the academic standards (i.e., minimum class rank) that are used to assess white applicants for admission when exposed to a treatment showing that first-year enrollment is trending toward an Asian-American plurality. In comparison, when exposed to the same treatment, white students raise the academic standards (i.e., minimum test score) that are used to assess Asian-American applicants.

Conclusion

The sociology of affirmative action has grown enormously over the last 20 years, but the research agenda remains vibrant and open.

The origins of affirmative action in employment are well understood. But further research seems needed to clarify its expansion in employment and its origins in higher education. Further research also seems needed to explain the contours and content of the partial retrenchment it has experienced. What would be especially useful are integrated accounts that trace the interplay between the state and national politics as well as connect landmark decisions in the federal courts with partisan politics, institutional strategies, and social and legal movements.

There is now a great deal of sociological research on the consequences and impact of affirmative action, but further research seems needed here as well. More studies of affirmative action in employment featuring high-quality identification seem desirable. It also seems valuable for sociologists interested in affirmative action and higher education to investigate exactly what kinds of policies and programs can help deliver the educational outcomes that are thought to flow from having a diverse student body. The source of black academic underperformance is also a topic worthy of additional research.

Finally, sociologists have a valuable opportunity to exploit a recent surge of interest in experimental methods to explore the apparent malleability and variability of public opinion on affirmative action.

Affordable Private Schools in Developing Countries

Pauline Dixon, Newcastle University, Newcastle Upon Tyne, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Affordable private schools have burgeoned in poor countries around the world. These schools provide education for the poor in urban and rural areas of developing countries. Children in the affordable schools typically outperform those attending government schools after controlling for selection bias, family background, and innate ability. This is at a fraction of the teacher cost of government schools. A new industry has set up around this market providing products specifically designed to improve quality and access. Aid agencies are now realizing the contribution affordable private schools can make to achieving quality education for all.

Affordable private schools provide education for children in poor urban and rural areas in developing countries (Tooley and Dixon, 2005b). Survey and census data gathered in slums and low-income areas around the world have revealed the presence of a large private school market that is providing education for the poor in countries such as Ghana, Nigeria, Kenya, South Sudan, Liberia, Sierra Leone, India, and Pakistan (Dixon, 2013). Research teams distinguish two types of fee paying affordable private schools. First, schools that operate under any official radar, functioning in an extralegal sector, which are termed unrecognized or unregistered. Secondly, schools that gain recognition from the government by 'supposedly' abiding by the 'on paper' regulations are known as recognized or registered. Although there are multiple rules and laws that have to be adhered to 'on paper,' these are often unattainable 'in practice' by those operating in poor areas owing to expense or unavailability of the requirement, for example, requiring a 4000-square meter playground in a cramped slum or teacher salaries being equivalent to that of government salary provision. The laws and rules generally do not target inputs that improve quality outcomes. In order to gain recognition status, which implies in most countries the school is able to run state examinations, owners pay unofficial payments, that is, bribes to educational officials, to gain recognition irrespective of whether the school meets the 'on paper' criteria (Dixon, 2003). The survey and censuses where researchers map the locations of affordable schools need to be carried out because unrecognized or unregistered schools do not appear on any of the official government or education department lists.

Affordable Fees

Affordable private schools have typically grown organically within the communities themselves; run by local entrepreneurs who have recognized a need by local children for education. These schools are accessible to the poor because the fees charged are affordable to those earning minimum wages. Families that send their children to these schools are typically employed as daily paid laborers, market traders, taxi drivers, construction workers, and fishermen or hold other manual labor positions. Parents may be illiterate even in their own language. In India, affordable private schools charge fees that amount to around 6% of minimum wage. In Africa it is generally higher, at an average of about 10–12%. These affordable private schools typically provide places for the 'poorest' in their communities by offering scholarships or concessionary places for those most in need (Tooley and Dixon, 2005b). The majority of schools are run for profit. Fees from parents are their main source of income. The government, NGOs, and religious organizations do not support this school management type.

Burgeoning Private School Sector

The number and proportion of affordable private schools is large in low-income areas and slum areas of Asia and Africa. In Pakistan, it is estimated that there are more than 47 000 private schools catering for about one-third of primary school-aged children (Andrabi et al., 2007). In urban settings of India affordable private schools can make up between 60 and 80% of school provision catering to around 65–70% of children. In rural India, some estimates imply that between 24 and 40% of children attend affordable private schools (Pratham, 2011). In Africa numbers are similar. In Lagos State, Nigeria, a large majority of children are attending these schools. In three districts of Lagos state, 540 schools were located of which 66% were affordable private schools. It is estimated that at least 75% of children in Lagos state are attending affordable private schools. The Ga region of Ghana is home to some half-a-million inhabitants of whom 70% live on or below the poverty line; 779 schools located during a census in Ga, indicated 75% being affordable private schools and 65% of children attending these schools (Tooley et al., 2005, 2007). Studies from India and Africa have shown more affordable unrecognized schools than government ones.

Longevity of Affordable Private Schools

These schools are not 'fly by night.' In Pakistan, such schools have been operating for more than 20 years where household surveys at the time found in Lahore a high proportion of children enrolled in private schools, even from the poorest families (Alderman et al., 1996). In Haryana, India, around

13 years ago affordable private schools provided poor parents with educational choices for their children (Aggarwal, 2000).

Teacher Salary and Qualifications

Teachers are paid less in the affordable private schools compared to teachers in the government sector. In India, teachers in affordable schools can be paid one quarter of the salary of a government school teacher. To teach in an affordable school, in practice, teachers need not have a teacher qualification or certificate. However, data have shown that in countries such as Pakistan and India the standard teacher resume characteristics have little bearing on student attainment (Aslam and Kingdon, 2007). What are more effective are teacher activity, retention of teaching staff, and the ability to fire those who are not effective.

English Medium in India

Parents in India choose the affordable private schools for their children because many purportedly teach all subjects in English. Most private schools in India are English medium, and parents believe that learning through English will help their children attain better opportunities after school with regard to employment and further education. Being able to communicate in English, parents believe will give their children a better chance to lift themselves out of poverty (Sen and Blatchford, 2001; Mitra et al., 2003).

Children's Achievement

Affordable private schools perform well compared to other school management types. Testing has been carried out with children in mathematics, English, and home language. Data have also been gathered on the pupils' family background, innate ability, as well as school and teacher characteristics in order to control for school choice, selection bias, and other variables that might affect achievement. Various analytical techniques have been used to analyze data, including multilevel modeling and the Heckman Lee procedure. In general, the results show that pupils in affordable private schools outperform those in government schools for a fraction of the teacher cost (Tooley et al., 2010, 2011; Pratham, 2011; Andrabi et al., 2010). In Pakistan, children from government schools perform 0.8–1.0 standard deviations lower on independently administered tests than do 'equivalent children in private schools'(Andrabi et al., 2010). Data from Pakistan show that children in government schools would need 1.5–2.5 years to catch up with children in affordable private schools (Andrabi et al., 2007).

Recent Developments

There have been several major developments in recent years in this space owing to the advancement in knowledge and information around the affordable private school's market. Currently, there are a handful of affordable school chains including the Omega Schools in Ghana, Bridge Schools in Kenya, and Empathy Learning Systems in India. The first Bridge school opened in 2009 and currently has around 70 schools in their network around Nairobi with a view to opening 400 in the chain. Omega schools opened their first school in 2010 and is a for-profit chain currently consisting of 30 schools charging a daily fee of 1 Ghanaian Cedi (around 60 cents). The daily fee allows much more flexibility for parents and includes lunch, uniform, books, and tuitions. Chains of schools benefit from economies of scale and are able to work on curriculum and pedagogy development as well as in devising and evaluating different methods of testing and assessment. Parents also know what they will receive from the 'brand.' The education company Pearson who also own the Financial Times and Penguin books has recognized the potential in chains of affordable private schools. Pearson have launched a fund called the Pearson Affordable Learning Fund which is investing in and providing support to organizations that focus on education solutions for the poor. Impact investors have now recognized the potential in the affordable private school's market. The supply of capital to improve quality and expedite expansion can now be accessed through companies such as Gray Ghost Ventures, Edify, Opportunity International, and the IDP Foundation. All are now investing in the affordable private school space. International aid agencies such as the Department for International Development (DFID) in the United Kingdom are now funding projects that focus on affordable private schools by improving their quality as well as access. Charities such as Absolute Return for Kids (ARK) in London are funding quality inputs as well as targeted vouchers and associated randomized control trials to augment knowledge around the effectiveness and potential of affordable private schools.

African Legal Systems

Gordon R Woodman, University of Birmingham, Edgbaston, Birmingham, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Many customary and religious legal systems were effective in African societies before colonization. The colonial powers added legal systems based on their own laws. Both types have continued to be effective since Independence and the introduction of written constitutions. Post-Independence state laws have been developed to strengthen state institutions and to promote nation-building. Post-Independence customary laws, observed by populations smaller than those of states but sometimes stretching across state boundaries, have adapted to modern circumstances. They are widely observed in the fields of family law, land law, and dispute resolution procedures, and state laws give them varying degrees of recognition.

Terminology

'African legal systems' means, for the purposes of this article, the bodies of interrelated legal norms and accompanying institutions of norm-creation, norm-finding, and norm-enforcement, which have a social existence in Africa. 'Legal norms' are taken to be social norms which are enforced by relatively strong degrees of coercion.

Customary and Religious (Nonstate) Legal Systems

Customary legal systems exist by virtue of the social observance of their norms, and not by the creation of their norms through state institutional processes, such as the enactment of legislation. Customary legal norms are observed because of a continuing but usually tacit understanding within a population that the bodies of norms to which they belong are to be accepted as obligatory. For the present purpose a practice need not have been observed for a very long period to be 'customary'.

Religious legal systems are for the present purpose a variety of customary legal systems, their distinctive feature being their derivation from systems of religious belief. In Africa the primary systems of religious law are varieties of Islamic law. In many communities, especially in North Africa and the Sahel region, the predominant law is *shari'a*, sometimes modified under the influence of other local customary norms (*see* Islamic Law).

The subjects of an African customary legal system (that is, the population that observes a customary law) virtually never coincides with the population that is subject to a particular state law. The population subject to a state law normally contains populations or portions of populations which observe different customary laws, while many groups of subjects of particular customary laws are divided into subjects of two or even more state laws.

Nonstate African legal systems vary widely, and almost any generalization about them is subject to exceptions. Perhaps the most distinctive feature of African customary legal systems is the frequency with which the parties to legal relations are communities of ascribed membership, especially of membership by descent, not individuals or other corporate persons as in western legal systems. Thus, for example, substantial interests in land are often vested in lineages or in communities comprised of several lineages. Marriage is often contracted by agreement between the lineages to which the bride and groom belong, with the consent of the bride and groom themselves, and creates legal relations between the lineages.

A customary law community often has an individual leader, instances of which range from the 'head of family' of the relatively small lineage to the 'chief' or 'king' of a large polity, such as Asante or Buganda, although there are also many acephalous communities. Leaders are determined according to customary legal norms. Although in some circumstances a charismatic leader may temporarily acquire personal authority and wield discretionary power, generally customary law imposes strict limits on the powers of leaders: the rule of customary law prevails widely.

Another common feature of customary legal systems is the nature of the procedures and principles governing the settlement of conflicts of interests and disputes. These are directed to the achievement of social peace and harmony within the community rather than the determination of legal rights. Dispute processes are less frequently instances of adjudication than of mediation or negotiation, in which there are social pressures on the parties to compromise.

State Legal Systems

The modern African state with its governmental and legal institutions is a product of colonization, with the possible exception of Ethiopia. The colonizing powers drew up by agreement between themselves the territorial boundaries of their African colonies, and these boundaries very frequently divided the territories occupied by populations observing particular customary laws. In most parts of Africa there was relatively little immigration from the colonizing countries, and everywhere the indigenous inhabitants remained in the majority. Nevertheless the colonial powers set up systems of government that resembled those of the metropolitan states, except that they did not provide for extensive popular choice of governments or other participation in government. The English common law was imported into the British colonies. Codes largely identical with those of France and Portugal were enacted in their colonies (Allott, 1960, 1970; *see* Sub-Saharan African Legal Traditions).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10111-4

The received laws shaped the institutions of the state legal systems, such as the courts, and provided bodies of law in fields, such as crime, contract, property transactions, and personal injuries. The technical and social knowledge necessary to administer this law in such roles as those of judge, legal advisor, legislator, and police officer were initially lacking in the indigenous populations. The lacuna was filled by colonial officers brought from the metropolis, some of them members of the professional legal community there, and others with some training and socialization in the ways of that community. Members of indigenous communities later obtained the training and assumed the social practices that enabled them to take over these roles. Thus the laws of the colonial powers became African legal systems. At Independence (achieved in most states between the late 1950s and the end of the 1970s) African rulers and administrators saw their aspirations and material interests as dependent on the continued effectiveness of these legal systems.

Those customary and religious institutions and practices that the colonial powers perceived to be inconsistent with colonial domination, such as primary allegiance to chiefs, they attempted to destroy or transform. Their policy toward other components of these indigenous legal systems varied, but often was to tolerate and sometimes even to encourage their continuance as alternatives to those of received law. Whatever the colonial state policy, customary laws continued to be observed concurrently with state laws. In this form of legal pluralism there was no unified hierarchy of norms. Individuals differed according to whether they gave general priority to the observance of state law rather than a nonstate law, or, gave priority to each on different occasions.

Within state law a further type of legal pluralism was formed. State legal systems gave recognition to African indigenous customary and religious legal systems. 'Recognition' here designates the policy whereby state legal systems treat the institutions or norms of customary and religious law as parts of the law of the state, giving effect to them and enforcing them in the same way as the institutions and norms of received law. Policies of recognition were adopted in some British colonies from the beginning, and eventually adopted everywhere. The forms of recognition can be analyzed as falling into two categories.

Institutional recognition of a customary or religious legal system occurred when institutions of that system were incorporated into a state legal system, as for example, when chiefs became administrative officials or judges of the state. This frequently happened in British colonies, in accordance with the policy of indirect rule which sought to govern colonies through native forms of government. With the abandonment of the policy from the 1940s this recognition became less significant, but it continued in a limited form. In other colonies it was adopted as a concession to local opinion, as well as for practical reasons. In all instances it has continued since Independence.

Normative recognition of a customary or religious legal system occurred when norms of that system were incorporated into the body of norms of the state legal system. State law might provide, for example, that rights in land could be transferred by procedures specified by norms of customary law, or that the inheritance of property might be determined by customary and religious norms. The incorporated norms then became enforceable in state courts. This also occurred in most African colonial legal systems, and also has continued to the present.

Customary and religious laws were not and indeed could not be 'incorporated' into state law without radical changes to their nature and content. The state has always excluded from incorporation some portions of customary laws, such as those providing for slavery, which came to be viewed as contrary to the fundamental values of the state once the European states themselves had abandoned the practices. Moreover, the acceptable elements of customary and religious legal systems could not and cannot be accommodated without reformulation. The institution of chieftaincy, for example, is transformed when its authority ceases to be derived from respect for tradition and communal identity, and becomes based upon the threat of coercion by state institutions. The forms of coercion of state institutions, such as the threat of imprisonment supporting an adjudicative decision, differ from the social pressure traditionally exerted upon disputing parties to agree to a compromise. Consequently the effect of normative recognition has generally been to compel behavior of a different type from that which would otherwise have occurred. Finally, the personnel of state institutions are frequently unfamiliar with customary or religious law and have 'recognized' norms which differ from those socially observed. Thus state institutions create new bodies of norms, 'official', 'lawyers', or 'judicial customary laws', which differ from the 'living', 'people's', 'folk', 'indigenous', or 'practiced customary laws' which have continued to be observed outside state administrations. Some legal historians consider lawyers' customary law to be an 'invention', bearing no significant relationship to preexisting social norms (e.g., Chanock, 1985; cf e.g., Woodman, 1985; Bennett, 2004).

Past and Present Trends in Legal Development

Legal development since the institution of the colonial state has reflected the considerable political and social changes which have taken place in Africa.

Changes in state public law, that is, those branches of the state legal system which regulate government, have generally been directed toward strengthening the state and elaborating the functions and powers of state executive bodies. From various times, the earliest being in the late 1940s, the state public laws have also provided for increasing public participation in government. The Independence constitutions contained rules for democratic and constitutional government. In the immediately following decades many states instituted one-party government, or experienced the violent overthrow of their constitutions followed by military rule. More recently internal developments and external, globalizing pressures have produced in most states trends toward constitutionalism, more democracy and accountability in government, and emphasis on environmental protection. These forces, and notably the formation of the African Charter on Human and People's Rights of 1986, have produced constitutional recognition of a wide range of human rights through judicially enforceable legal provisions.

Nation-building has been a major objective of constitutional orders. The boundaries of modern African states, inherited from the colonial powers, contain different ethnic and religious groups, each with its own culture, customary law and language. These boundaries have in very few instances been changed in post-Independence Africa. However, the individual citizen's

loyalty and sense of belonging are often directed primarily to the ethnic or religious group to which they belong. Constitutional provisions, in an effort to create a sense of national identity, have prohibited discrimination on the ground of ethnicity, language, or religion in many activities, including the selection of members of state institutions and political organizations. This has been seen as necessary to economic and social development, as has the principle of indigenization of positions of economic or social power. There have been increasingly determined attempts to improve the legal position of women, who are seen as seriously disadvantaged by traditional laws and practices, and of children. However, the normative recognition given by state law to customary laws in the colonial period has generally been continued, and in some instances even confirmed by constitutional provisions. In contrast, recognition in state criminal law of customary law has never been extensive, and today the state criminal law is usually contained exclusively in state criminal codes, together with other written laws specifying minor offences.

Developments in public law have generally increased the functions of state law as a regulator of social behavior. All of the trends just noted, and the long-term tendency toward western-style governmental systems have been accompanied by a decline in the African state's use of customary institutions, such as chieftaincy, and so of the strength of these institutions. Nevertheless, the state is still not the sole, unchallenged legal authority. It remains notoriously ineffective in regulating the daily lives of most citizens outside its own bureaucratic institutions. Even within these institutions, instances of corruption and abuse of power show that state officials are not punctilious observers of state law. One global policy may also have reduced the scope of state law. The structural adjustment policies which the World Bank and International Monetary Fund set in the late twentieth century as conditions for economic aid tended to reduce state involvement in economic activity in favor of private business institutions, thus strengthening against the state law forces in the international market and global political influences.

In the fields of private law, changes are visible in the content of received law, living customary law, and lawyers' customary law.

Received private law has been continuously changing both in the European countries of origin and in African states. State laws required received law to be adapted to local circumstances by the courts and legislatures. But decision makers have also asserted the value of transnational uniformity in the principles of the common law and civil law, respectively. Decisions and textbooks from the countries of origin of received laws have been followed in African jurisdictions. Even in the legislative reform of received law the best legislative model is sometimes held to be the latest legislation in the country of origin, in fields as diverse as company and divorce law. On the other hand, in legislation concerned with economic development, such as that regulating foreign investment, there has there been significant innovation.

The extent to which received law is observed has increased as a result of some aspects of social change. Policies of 'modernization' have been accompanied by a general official belief that the application of Western laws gives effect to the principles of the market economy (*see* Law and Development). To the same effect has been the growing involvement in the global economy of private individuals and businesses through the export-oriented development of cash crops and extractive industries. Education and technology have been taken from the West as well as being locally developed. The same tendencies have produced and are in turn reinforced by the emergence and growth of national legal professions. Nevertheless, in activities such as the contracting of marriage, the acquisition and use of lineage assets, and land use, most people still choose to act under customary law.

Systems of living customary law have never been static, and have changed and developed to meet new circumstances, first in the colonial periods, and then since Independence. The individual has gained more autonomy, having today the capacity to hold extensive property and enter into weighty transactions independently of their lineage. Legal transactions are today more often determined by market forces, rather than by standard customary terms. Written records are more commonly used, and more norms have been developed to guide relations between members of communities and outsiders. New bodies of customary law have been formed, especially in the vastly expanded urban areas where religious, professional, welfare, and self-help communities with their own customary laws have been created. The primary fields in which living customary laws receive significant observance are those of family law, property (especially land) law, and processes of dispute resolution.

Lawyers' customary law has also changed, in that norms which the state will recognize and enforce as customary law have been progressively elucidated and embodied in judicial decisions, restatements, and textbooks. To some degree the reformulation entailed in these processes has been in the same direction as changes in living customary laws. However, the processes have also had a conservative effect, because a norm embodied in an authoritative pronouncement is not easily changed thereafter in response to changes in social circumstances. The gap between lawyers' customary law and living customary law could thus grow, although measures are being taken in some jurisdictions to avert this trend by developing lawyers' customary law to be a more accurate reflection of living customary law. Another major development in lawyers' customary law has been the extensive amendment to some areas by legislation. Land laws in particular have been amended in attempts to balance competing claims to land use while also promoting economic development and inhibiting environmental damage. Here the extent to which living customary law diverges from state law is a function of the extent to which the state is able to make its legislation effective.

Current and Future Issues in Legal Development, Theory, and Research

Current lawmaking by states is directed toward a number of practical problems. There is a search for constitutional forms which will maintain stability against interethnic and interreligious conflict, and other forms of civil disorder. In some states the relationship between customary and religious legal systems and state law has become an even more acute issue since the constitutional entrenchment of human rights, with which some nonstate laws appear incompatible. Globalization intensifies certain issues. State law may be developed to protect national economic independence against the power of international

businesses and institutions, such as the World Trade Organization. State law may also introduce institutions which can safeguard and assist economic development in the face of new threats from natural and artificial disasters, such as climate change and the AIDS epidemic.

In the past few years international development agencies have increasingly fostered research and discussion to determine whether customary laws should be treated as factors in development, and taken into account in adjusting and improving development programs, rather than simply obstacles to development (Tamanaha et al., 2012).

Research into African legal systems has in the past been carried on within several disciplines. The study of customary law has used the methods of anthropology and sociology, of state law those of legal analysis, and of Islamic law those established specifically within that scholarly tradition. Today there is more interdisciplinary understanding. One consequence is renewed concern with fundamental questions about the concept of law, especially that as to whether customary and religious normative orders are truly law. These debates may also raise doubts as to whether it is appropriate to speak of 'systems' of law.

With indigenization and expansion of the African civil service and academia, most research into African legal systems will in future be conducted in Africa by African scholars. It will be closely concerned with the practical problems just mentioned. However, it is likely that the more fundamental theoretical issues will continue to inspire and to be investigated by an international community of scholars.

Abstract

The study of African culture follows four phases during each of which the focus, basic material, and interpretive framework has been quite different. Within and between these phases there has been a great deal of contention: in part because scholarship was dominated for a long time by Europeans rather than Africans, and in part because the sources are so vast and so relatively difficult to study. In the earliest phase, before the era of academic disciplines, missionary writings, and travelers' writings developed a contrastive model, where Africa was the antithesis of Europe. The first systematic work was based on a natural historical method of study, involving the collection and classification of cultural items, particularly material and artistic ones. The anthropological approach to culture as the entire lifeworld of a community, integrated by key propositions that reflected the social structure, succeeded the previous approach in the 1920s. Research involved field studies of ideas and materials in use in social life, and thereby moved away from the arts, music, and technical inventories toward the ideas that underlie and give meaning to them. Since the 1960s, study of a current and expanding creative production that relates to the present joys and dilemmas of life has replaced the traditional 'worldview' approach to culture. A great flowering of scholarship has been possible on the basis of new technologies of recording and a broad approach to culture itself. The historical connections between Africa and the rest of the world have replaced the conceptual separations, informing a new scholarship on diasporas. Most recently even the icons of traditionality are being restudied in light of the influences of global history.

The study of African culture follows four phases during each of which the focus, basic material, and interpretive framework has been quite different. Within and between these phases there has been a great deal of contention: in part because scholarship was dominated for a long time by Europeans rather than Africans, and in part because the sources are so vast and so relatively difficult to study. In the earliest phase, before the era of academic disciplines, missionary writings and travelers' writings developed a contrastive model, where Africa was the antithesis of Europe. The first systematic work was based on a natural historical method of study, involving the collection and classification of cultural items, particularly material and artistic ones. The anthropological approach to culture as the entire lifeworld of a community, integrated by key propositions that reflected the social structure, succeeded the previous approach in the 1920s. Research involved field studies of ideas and materials in use in social life, and thereby moved away from the arts, music, and technical inventories toward the ideas that underlie and give meaning to them. Since the 1960s, study of a current and expanding creative production that relates to the present joys and dilemmas of life has replaced the traditional 'world view' approach to culture. A great flowering of scholarship has been possible on the basis of new technologies of recording and a broad approach to culture itself. The historical connections between Africa and the rest of the world have replaced the conceptual separations, informing a new scholarship on diasporas. Most recently even the icons of traditionality are being restudied in light of the influences of global history.

Introduction

The concept of culture is one of the most disputed in the social sciences, and nowhere more so than in African studies. The classic study of culture rested on the study of the main media of expression: music, art, material forms, and (above all) language and the written expression of thought in literature, philosophy, and theology. Texts were central. In the foundational era of African Studies, in the nineteenth century in Europe, Africa was assumed to have no texts at all. Its arts of music, performance, and oral poetics were thought to be different in kind from text-based culture. They were performative and multimedia rather than abstract and specialized. Hence their designation as 'primitive', which survives in the occasional museum and art gallery. The basic collections were, therefore, of sculptural art and material culture, which were relatively accessible even to amateur collectors, and which were assembled during the competitive rush for acquisitions by museums in the late nineteenth and early twentieth centuries. Even for specialists in the study of 'primitive cultures', however, techniques for reproducing their non-written cultural forms – such as tape-recording, photography, and film – were still too clumsy and fragile at that time to produce a solid and reliable corpus for study. The analysis of African cultures has grown and changed, therefore, with changes in thinking about culture in general, in the technologies of scholarship, and in the place of Africa in the world. These changes are discussed in general and then their enduring contributions are summarized.

Historical Overview

Since the late nineteenth century in the systematic study of African culture, scholars and artists have struggled to rework the foundational legacy as new study techniques, approaches, and colleagues appeared on the scene. Three major changes have erased the categorical distinction between literate and oral/performative culture. First, new recording technologies have made performative culture amenable to the kinds of analysis given to texts in the past, and have made primary sources more widely available for secondary analyses. Second, and at the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10112-6

same time, modern cultural studies in Europe has moved closer to African studies by embracing a much wider range of arts and performance than in the past, including multimedia work, and by looking at how different media can draw on the same forms and themes. Still using textual methods, they now include popular culture, film, clothing, and other expressive forms, and they link style, substance, and concepts of authorship to social context far more than was done in the classical mode. Finally, the African library of written texts has expanded greatly in the twentieth century. Far more written forms from the past are now recognized than were acknowledged in the classic period, including voluminous sources written in Arabic script and certain sculptural, geometric, and musical forms that are now realized to encode verbal content (e.g., Roberts and Roberts, 1996). The other source is current artistic production. There is a new corpus of literature, music, and the arts that is not 'traditional', but rather responds to the situation of modern life, including the global marketplace. The new expansion in Africa includes African scholars' studies of their own past and present art forms, working from their own languages, and this has contributed new expertise and a new set of ideas to the international arena.

These changes from the classic, classificatory, study of culture to the current expansive incorporation of varied and linked forms are still being worked out and they are still contentious. At the same time, the sheer enormity of the task of adequate study of African cultures is realized increasingly. Only in the European view of the confident, progressive industrial era could the whole continent and its millennia of history be grouped together into a single category as 'Africa'. Africa is the cradle of humanity; its cultures have very deep histories; its population is also highly diverse. There are about 1000 African languages spoken. More than was originally understood also benefit from written works. Even the popular icons of Africa that have been studied for decades – such as masks, body decoration, 'fetishes', and drumming – are far richer as traditions than the scholarship can yet do justice to.

With these provisos about the completeness of the record, the history of cultural study can be divided schematically into four broad successive phases. The first comprises the early missionary and traveler documentation, up to the mid-nineteenth century. The first systematic efforts at documentation (a second phase, from the late nineteenth century up to World War I) were carried out in the natural history style. Nonliterate cultures were studied by collecting cultural items, and describing and classifying them according to the taxonomy of the collector. The third phase was anthropological, and lasted more or less unchallenged from about 1920 to about 1960 (the time of political independence from European colonial rule). It was devoted to the idea of cultures as coherent systems of thought and representation, where all the elements of the life ways of a community (judged either by their common language or common membership in a political community) could be related to each other. The fourth and present phase (from about 1960 and continuing) illuminates cultural themes and techniques by drawing on the classic and modern humanities. Here culture is seen from within, as a field of imagination and debate. There have been major achievements in all four phases, each of which has posed key questions for comparative knowledge, general theory, and public debate.

Phases in African Cultural Studies

Missionary Understandings and Older Sources

The idea that Africa and Europe 'framed' the human experience – initiated and culminated it, expressed two ends of a spectrum of biological and cultural experience – predates the disciplinary study of the continent and has been extremely persistent in Western thought. Evidence about Africa from before the nineteenth century is both sparse and problematic. Nevertheless, these sources set agendas. Writings from that period, by Europeans in their own languages, are now seen as having 'invented' (Mudimbe, 1988) an Africa that is fundamentally contrastive with the West. This conceptualization still informs the general Western lexicon about Africa, but it has been repeatedly challenged by scholars.

African philosophers and scholars outside of the European mainstream have insisted on a return to older sources, to question the basis for the contrastive model. Most prominent has been the Senegalese thinker Diop (1955), who argued for the Egyptian origins, pan-African connections, and historical unity of African cultures, as against a 'primitive' and racialized conception. Painstaking scholarship in several disciplines continues, linking evidence from the old sources to new findings on, for example, the long history of urban cultures, monies, and trade, the use of Arabic script, and fractal geometric and other mathematical concepts in African design and divination (Eglash, 1999). Archaeology and paleontology examine yet earlier traces of cultural life, not only through fossil remains (for the very distant past) but also in rock paintings, house and burial sites, the remains of iron and copper works, and so on.

It was, however, the prevailing contrastive model that was pushed in new directions by the first disciplinary scholarship about African culture.

Culture and Natural History

A passion for creating encompassing classifications of all of life gained momentum in European intellectual circles during the nineteenth century. Other cultures and their attributes were seen as part of the phenomenal world, to be treated similarly to other life forms. The actual process of collecting involved human and political encounters of a depth, complexity, and problematic nature that is still being studied (Fabian, 2000). Some objects were seized during the punitive expeditions of colonial conquest from the 1880s until about 1910; some were accumulated during Christian conversion and the outlawing of the ritual cycles in which they were used; others were acquired by organized museum expeditions, where the items were bargained over and paid for. Hundreds of thousands of pieces – some of great artistic value in the West and religious value to the populations themselves, and others of technical interest only – arrived by one or other of these routes in American and European museums, where the vast majority remain. Some pieces have been missed gravely; one or two have been returned. To their lasting credit, however, some of the collectors were attuned to the breadth and completeness of their collections and to the originality of the material so that they remain a spectacular resource for scholars from all nations and fields. Some collectors also kept acquisition records, which can still be

gleaned for contextual understanding of both the collecting and the objects themselves (Schildkrout and Keim, 1998). And a few, such as the missionaries George Schwab (1947) with George Harley, wrote books about the cultural lives of the people who created and used the objects.

The emphasis was on material culture, with some notable photography of items in use and of daily life in general. It would be hard to exaggerate the amount and the variety of the African material culture in Western museums: everything from divination trays to fish traps, enough spears to arm small militias, carved spoons, blacksmiths' tools, indigenous currencies, cloth, talismans, and 'fetishes'. Culture, in the natural history mode of thinking, was everything that people produced by virtue of learning, from the most intricately symbolic to the most pragmatically functional. The very large number of works that could be classified as 'art' had a further destination than the natural history museum. Some went into an art market that made its own selective choices of value. There are African works from this period that are now considered masterpieces, valued in the hundreds of thousands of dollars. The asymmetric geometry, the nonnatural figurative representations, the brilliant colors, and the general vitality of these pieces were a major influence on modernism in European art. The power of modernism, in turn, fixed these particular pieces in the mind of the public as icons of African aesthetics.

The recognizability of African icons has turned out to be a very mixed legacy because it has made innovation more of a struggle. During the museum era, the icon of African music became drumming, of art became figurative sculpture and especially masks, of architecture became what is still referred to in popular parlance as the 'hut', of body decoration, scarification, and so on. The following phase of cultural study involved an effort to break out of this straightjacket, and above all to place the elements back into the context of life-as-lived. Culture was not just a product of learning, but a means of articulating a world view.

Culture in Anthropology

The era between World War I and political independence, about 1920–60, was the period of effective colonial rule in Africa. During this time, conditions were settled enough for scientists to stay for long phases of their careers, in some places setting up permanent research institutions. By this time, anthropology had become committed to studying societies and cultures as wholes. Where political and cultural lives were lived through oral and performative media, this meant long-term residence with them: to collect the texts, case studies, genealogies, maps, calendrics, and so on from which such an integrated model could be deduced. Political and medical conditions allowed, and intellectual aspirations promoted, the practice of field research, usually carried out for at least a year.

If cultures are conceptualized as integrated wholes then the key to their understanding must be the general concepts that animate and link the separate elements, domains, and performances. So this era of cultural study moved away from the objects, to place greater emphasis on ideas, symbols, and general principles. Particular emphasis was given to the ideas that motivate social life rather than those expressing aesthetic values: the concepts underlying kinship and political identity, religious symbols and practices, and philosophies of the composition of the lifeworld. In fact, cultural studies in European scholarship about Africa moved away from materiality altogether. The key works were about concepts of causation (Evans-Pritchard's eternal classic entitled *Witchcraft, Oracles and Magic among the Azande*, 1937), symbolic power (Turner, 1968), kin relations (Fortes, 1945), cosmology (Griaule, 1948), and philosophy (Tempels, 1946). Scholars of Africa, such as Douglas (1966) made major contributions to general culture theory, by linking conceptions of what is pure and what is dangerous to specific ambiguities in social structures. In a sense, this period replaced a notion that African cultural 'genius' lay in the figurative arts with an 'African Genius' (Davidson, 1969) that lay in the capacity to organize complex social life without the state domination characteristic of Europe. African cultural studies illuminated the study of society in general.

Culture Today

The rebellion against this approach, both within anthropology and beyond, was a rejection of the implication that any cultures could be studied as if they were 'traditional', in the sense of closed, unchanging, and unchallenged from within. The arts resumed center stage, not as iconic objects but as active creativity: emergent novelty, specific named authorship, audience reception, and constant revision and re-creation. This was culture as a field of imagination and its students included its creators: the new novelists and artists of independent Africa, commenting on the present. The humanities became prominent again. Greenberg (1972) suggested a highly persuasive language classification, which changed the history of the modern peopling of the continent. Vansina (1961) innovated in historiography by promoting oral history, which helped to open up a new effort on orature in general. Scholars of their own languages, such as Abimbola (1976) of Yoruba, Kunene (1979) of Zulu, and Ngugi wa Thiong'o (1986) of Gikuyu, worked on their own language creativity. Novelists, poets, and filmmakers – such as Achebe (1958), Soyinka (1964), and Sembene (1960) – used modern media to express the challenges of modernity as well as writing very influential critical works about culture and national life. New popular art forms, such as juju and highlife music, the Yoruba traveling theater, textile fashion, and hairdressing animated local engagement with the future and became subjects of study in the academy. Hountondji's (1977) attack on 'ethnophilosophy' both opened a new era of African philosophy and symbolized the break in cultural studies from the community-based traditionality of earlier anthropology. The center of gravity moved away from communities and toward the study of expertise, innovation, and urban life.

In the 1990s, the cultural scene in Africa became yet more diverse, including new architecture, jazz, video, and new versions of Christian thought and expression. The vast African diasporas in the Americas and elsewhere, from both the era of the slave trade and new global mobility, are now considered to be part of an African cultural ecumene. In turn, African history has been revisited to show how long and how widely Africa has been connected to the rest of the world, with lasting effects on many aspects of life – from cultigens to religious

expression (Blier, 1995) – that were once thought to express the very 'nature' of Africanity. These social geographical observations are matched by a new appreciation of the openness of cultures within Africa to novelty and originality, whether developed from within or borrowed from without. In a world era when dynamism is in full play, among ordinary people as well as cultural elites, this makes the study of Africa's long history, popular ebullience, and varied multiplicity the unique contribution of African Studies to the study of culture: to an understanding of cultural hybridity, memory, power, and the importance of local texts (newspapers, diaries, early novels, and records) and the vernacular popular arts (Barber, 2007)

Diaspora Studies have been pioneered by peoples of African descent: in Brazil, the Caribbean, Europe, and undoubtedly in a growing crescendo elsewhere in the world (Matory, 2006). The 'retentions' and reconstitutions of African culture by the continent's descendants who had been utterly stripped of every object, every community relationship, and any common African language during the era of the slave trade has remained a challenge to understanding. Herskovits's (1941) pioneering work in the 1930s stood for a long time at a tangent to cultural scholarship, which remained continent-based. The return of African-American cultural forms, such as hip-hop (Shipley, 2013), to present-day Africa became another theme. As South Africa's arts opened up to world appreciation, the designs for life and the market among the ordinary people took on a new profile (Fraser, 2002). Politically and intellectually, global attention to Pan-Africanist political and social thinkers, such as Fanon (Gibson, 1999), grew. In the 1990s, these themes were reopened, and in the process African cultural studies became trailblazing in the study of global networks in artistic and intellectual life, and of memory and continuing creativity in diaspora cultures.

Abstract

Health has been defined by the World Health Organization as a condition of complete physical and psychological wellbeing. In common usage the term 'good health' is employed to mean that there is present no major manifestation of ill-health, and this is also the most satisfactory way of scientifically determining the situation. The most clearly defined outcome of ill-health (or morbidity) is death (or mortality), because it can be most certainly defined and measured, and because in its irreversibility it is an index of the most extreme ill-health. This article focuses on mainland sub-Saharan Africa plus the large island nation, Madagascar, omitting the smaller islands of the Indian and Atlantic oceans with their mixed historical, ethnic, and cultural backgrounds. All of these have lower mortality than any mainland African country and most are richer. The advances in health research since the mid-twentieth century are outlined. From 1950 to 1985 mortality declined and health improved markedly in the region, if not quite as rapidly as elsewhere in the world. Since 1985, however, sub-Saharan Africa, in marked contrast to all other developing world regions, has experienced a major health crisis. It began with problems in sustaining economic growth, which led to both a fall in health investment and the acceptance of structural adjustment programs where the 'consumer pays' principle was applied to both health and education services. Mortality decline almost ceased. Then, parts of the region, conspicuously East and Southern Africa, were afflicted with an AIDS epidemic of far greater intensity than any other world region. Mortality is now rising throughout East and Southern Africa to such an extent that Botswana and Zimbabwe anticipate a drop of 20 years in their life expectancies between the late 1980s and the first years of the twenty-first century. The improvement in health since the beginning of the twentieth century has been a product of better health services, more universal education, the growth of a market economy, changes in attitudes towards children, and other factors. Many of these factors are at present under threat, and this combination is intensifying the African health crisis.

Health has been defined by the World Health Organization as a condition of complete physical and psychological wellbeing. In common usage the term 'good health' is employed to mean that there is present no major manifestation of ill-health, and this is also the most satisfactory way of scientifically determining the situation. The most clearly defined outcome of ill-health (or morbidity) is death (or mortality) because it can be most certainly defined and measured, and because in its irreversibility it is an index of the most extreme ill-health. This entry will focus on mainland sub-Saharan Africa plus the large island nation, Madagascar, omitting the smaller islands of the Indian and Atlantic oceans with their mixed historical, ethnic, and cultural backgrounds. All of these have lower mortality than any mainland African country and most are richer. The advances in health research since the mid-twentieth century are outlined.

Researching Africa's Health Levels

At mid-twentieth century sub-Saharan Africa was assumed to be the unhealthiest region in the world, in spite of an almost complete lack of data to confirm this view. That confirmation was to be achieved later by reconstructing the situation with data from subsequent research, which showed that as late as 1950–5 the region was characterized by a life expectancy at birth of only 37 years (United Nations Population Division, 1999). The problem in making such estimates was a complete lack of vital registration, and of usable mortality and morbidity information in censuses and demographic surveys. Comprehensive national counts of deaths or illness are still not available anywhere in the region.

This problem of inadequate data has been overcome in three ways:

1. The so-called 'indirect methods' of estimating mortality (and fertility) levels from inadequate data have been invented by William Brass and colleagues associated in later years with the London School of Hygiene and Tropical Medicine, while the stable and quasi-stable population model approach was developed by Ansley Coale and colleagues at the Office of Population Research, Princeton University. At first the 'Brass' methods provided estimates only of child mortality, but later techniques were developed for adult mortality, although the latter results were usually less secure.
2. Censuses and national sample surveys with questions allowing indirect or even direct estimates of vital rates were developed. The first censuses with questions on births and deaths were those in British East Africa in 1948. From the 1960 census round, the United Nations assisted African censuses. From 1954, demographic sample surveys were conducted in most francophone African countries. Subsequently, many African countries participated in the great international survey programs: the World Fertility Survey (WFS) (which contained mortality questions) from 1975 and its successor, the Demographic and Health Surveys (DHS) from 1985. Nevertheless, by the year 2000 there still had been no adequate censuses or surveys of the Congo (Democratic Republic) or Angola, and only preliminary reports had been issued for the DHS surveys of South Africa and Ethiopia.
3. High-intensity surveillance projects had been established in a range of areas. These provided demographic and health

information and were often the sites for intervention projects. They included largely demographic projects such as the Sine-Saloum (1962–6) and later studies in Senegal, and those with greater attempts to investigate health: Pare-Taveta, Kenya and Tanzania (1954–6), Keneba, Gambia (1956 onward), Danfa, Ghana (1969–74), Malumfashi, northern Nigeria (1974–9), Machakos, Kenya (1974–81), Kilombera, Tanzania (1982–8) and Navrongo, Ghana (1993 onward). All programs measured health, mostly by mortality or survival measures, and all involved collaboration between African and outside institutions. African demographic estimation was the most challenging in the world, and the new techniques developed to meet that challenge were employed subsequently in other parts of the developing world and by historical demographers.

The data released from these investigations were employed by a succession of research programs:

1. The African project of Princeton's Office of Population Research analyzed the results from predominantly francophone African demographic surveys and anglophone African censuses from 1961, and published *The Demography of Tropical Africa* in 1968. Its major contribution was its fertility estimates, and those on mortality were largely confined to infancy.
2. The International Union for the Scientific Study of Population (IUSSP) in the mid-1980s commissioned papers on African mortality change for a 1987 conference and published *Mortality and Society in Sub-Saharan Africa* in 1992.
3. The American National Research Council's Committee on Population established a program on the population dynamics of sub-Saharan Africa in 1989 and published *Demographic Change in Sub-Saharan Africa* and five other volumes in 1993.
4. From the late 1980s the World Bank commissioned studies of the health of sub-Saharan Africa and in 1991 published *Disease and Mortality in Sub Saharan Africa*. The first part of the book was constituted by studies of child and adult mortality and child malnutrition drawn from WFS and DHS data, the second part by studies of specific ailments from miscellaneous sources, and the third part by reports on morbidity and mortality from the various surveillance projects.
5. A collaborative analytical program of persons working in African universities and institutions on West and Middle Africa resulted in 1975 in the publication of *Population Growth and Socioeconomic Change in West Africa*. In it, Cantrelle developed his thesis on tropical mortality (discussed below).

Some African research themes have a strong behavioral component. Studies of the impact of parental education, especially maternal education on child survival began in the region (Orubuloye and Caldwell, 1975; Caldwell, 1979; Farah and Preston, 1982), and have since become numerous elsewhere. The AIDS epidemic has brought demographers and other social scientists to the study both of AIDS mortality and of sexual relations and other aspects of HIV transmission (Cleland and Way, 1994; Awusabo-Asare et al., 1997).

Health in sub-Saharan Africa has not been a major feature of social science literature, probably because the data have been elusive and difficult to interpret. It has constituted 7.8% of all articles in *Social Science and Medicine*, 2.5% in *Population and Development Review* and, except for anthropological accounts of traditional healing practices, none in *Africa*. The latter point underscores the fact that the major social science input into African health research has been by demographers. Biomedical researchers have undertaken research on specific diseases. The balance of this article summarizes what the research reveals about African health.

The Health Situation

The first reliable estimates of sub-Saharan mortality were for the late 1940s and early 1950s, and were for infants, and then young children, made by adjusting mothers' reports of their children's deaths. These revealed infant mortality rates (deaths per 1000 births during the first year of life) ranging in most of francophone Africa between 200 and 275 (and probably equivalent to life expectancies ranging from 25 to 35 years). At the district level, Mopti in Mali and Luanda in Angola recorded infant mortality rates of 350 and 329, respectively, showing that one-third of all births resulted in deaths during the first year of life. In contrast, Kenya recorded an infant mortality rate of only 132 (a life expectancy around 45 years) and two of its districts, Central and Rift Valley Provinces, registered rates under 100. Subsequent studies increasingly involving life histories, many summarized by Althea Hill, showed infant and child survival improving nearly everywhere until at least the 1980s. West African mortality was higher than that of East and Southern Africa, but convergence was taking place. As appropriate questions were added to surveys, advances were also made in the study of adult mortality, which fell consistently until the 1980s. Thereafter, the decline became much slower in West Africa, and halted or reversed in East and Southern Africa (Timaeus, 1999).

At the end of the twentieth century (1999) sub-Saharan Africa's life expectancy was 49 years, with male expectancy around 48 years and female 50 years. This compared with 61 years in South Asia, 64 years in North Africa, 65 years in Southeast Asia, 69 years in Latin America, 72 years in East Asia, 73 years in Southwest Asia, and 75 years in industrialized countries. With 9% of sub-Saharan African babies dying in the first year of life, and 15% in the first five years, the region's infant and child mortality was also the world's highest. Sub-Saharan Africa's life expectancy compares with that in Western Europe at the beginning of the twentieth century, suggesting a health lag of about 100 years. Within sub-Saharan Africa, Southern Africa recorded a life expectancy of 56 years, West Africa 52 years, Central Africa 49 years, and East Africa 44 years, the latter's poor performance being a recent product of the AIDS epidemic. National levels ranged from 55 or more years in Ghana, Liberia, South Africa, and Cameroon to 42 years or less in Malawi, Swaziland, Botswana, Zimbabwe, Niger, and Ethiopia. Such low levels as those for the last-mentioned countries are no longer found anywhere else in the world.

Past Mortality Trends

If tropical African population growth was almost stationary before the European partition of the region in the 1880s, then stable population calculations suggest that life expectancy was around 20 years. Alternatively, if, as has been suggested, the European presence on the coast had allowed the adoption of new foodstuffs permitting the denser settlement of the forest and other wetter lands, thus leading to a population growth rate as high as 0.5% per annum, life expectancy may have risen to around 23 years. In any case, mortality was, as traders on the west coast knew, the highest in the world, with malaria, yellow fever and other insect-borne diseases protecting the land from European settlement of the type that had occurred in Latin America. These mortality levels are not much greater than the demographic surveys of the 1950s and early 1960s found persisting in some remote rural areas of the West African savanna.

The Second Half of the Twentieth Century

Mortality estimates spanning the second half of the twentieth century, constructed by the United Nations Population Division (1999) from the research findings described above, are shown in **Table 1**. Such estimates can hardly be exact but they are probably reasonably close to the truth. They are compared with estimates for the world and selected other developing regions.

What emerges from **Table 1** is that sub-Saharan Africa is a healthier place than it was half a century ago. By the end of the twentieth century its life expectancy was above that of the world as a whole at mid-century, and only a little behind that of Latin America at that time. Nevertheless, it had fallen further behind every other world region. The most appropriate comparison is with south Asia, which has a somewhat lower per capita income than sub-Saharan Africa (and, taking purchasing power into account, a lower per capita parity purchasing power) and a slightly higher level of female literacy. In 45 years, Africa's life expectancy rose by 12 years, compared with 23 years in south Asia.

Table 2 explores the African health failure further. Neither sub-Saharan Africa nor North Africa participated to the same extent as Asia and Latin America in the great leap forward in reducing mortality that characterized much of the world during the two decades following World War II. Nevertheless, sub-Saharan Africa's record in health advancement was moderately successful until the 1980s, but since about 1985 there has been little health advance at all.

The relatively limited sub-Saharan African success in health up until the 1980s can be at least partly explained by the fact that ecological and other conditions meant that it was the only major world region that completely failed to reduce the level of malaria. Since the 1980s two other factors have also been important. The first was a slowdown in economic growth that necessitated the acceptance of 'structural adjustment' policies: in many countries, investment in the health sector almost ceased, and charges for government medical services were instituted. The second factor was the arrival of the AIDS epidemic with an intensity experienced nowhere else in the world.

All parts of sub-Saharan Africa have experienced a deceleration in health improvement, but this has been spread unevenly, as **Table 3** shows. The health situation in the region had been described as one improving along a diagonal with the lowest levels in the northwest of West Africa and the highest levels in Southern and East Africa (see Feachem and Jamison, 1991: pp. 31–2). Largely as a result of the AIDS epidemic, this situation has been reversing, and by the 2010s West Africa may have the highest regional life expectancy south of the Sahara.

A very similar experience characterized trends in infant and child mortality rates. Sub-Saharan Africa's infant mortality rate in 1950–5 has been estimated as 176 deaths per 1000 births, with the south Asian rate at 186. By 1995–2000 the sub-Saharan African rate was 93 compared with a south Asian rate of 73. The child mortality rate compared even more badly; in 1995–2000 it was 152 in sub-Saharan Africa (i.e., 15.2% of births resulted in a death before 5 years of age) compared with 96, or less than two-thirds the African level, in south Asia. The explanation is what Cantrelle (1975) called the 'tropical pattern,' and others have termed the 'African pattern.' When Cantrelle was writing, not only was infant mortality in tropical Africa high, but almost as many deaths occurred to each cohort of births between their first and fifth birthdays as during the first year of life. That fraction has now fallen to 63% (although it is still 73% in West Africa) compared with 32% in south Asia. The reasons for very high one-to-four- year-old mortality in tropical Africa are probably the high level of infectious

Table 1 Life expectancy at birth (in years), 1950–2000 and per capita income (in US$), 1997

disease affecting that age group, poor weaning practices, and unsatisfactory foods available for weaning.

Why Did Health Improve?

It seems likely that life expectancy climbed by about 15 years between the 1880s and the early 1950s, and then by another 11 years in the next three decades. The reasons are complex, and the use of modern medicine is only part of the story.

Much of the explanation for mortality decline in the first period was probably the organization brought about by colonial governments. Inter-ethnic and individual violence probably declined. People were separated from others when plague struck, and from wild animals to curb sleeping sickness. Roads and railways helped to usher in a market economy which distributed food, and medicine, more widely. Capitalism and education increased individualism and made it likely that greater initiatives would be taken to prevent or cure illness. Immunization, led by smallpox vaccination, eventually brought the great epidemic diseases under control. Yellow fever has almost vanished, and cholera levels have declined. Digging drains and oiling stagnant water reduced malaria in towns, and mosquito nets partly protected colonial and local elites.

There was a slow spread of government and missionary hospitals. Although there is debate about the impact of modern medicine on poor, predominantly rural societies, a comparison of two areas of similar socioeconomic levels in Nigeria showed that the one which had possessed for a generation a small, adequately staffed and supplied hospital offering free services was characterized by a life expectancy 12 years greater than the area with no facilities (Orubuloye and Caldwell, 1975). The treatment of water supplies, usually in urban areas and often inadequate, has improved, but is still often woefully bad. Better sanitation and hygiene practices have doubtless also reduced mortality. By the 1990s, Demographic and Health Surveys were reporting that about half of all countries had a majority of children immunized against tetanus, diphtheria, and pertussis (whooping cough), while the coverage against measles (a major killer in the region) was increasing and the incidence of poliomyelitis was declining steeply. But morbidity and mortality from diarrhea and pneumonia were still high. Malaria was almost as bad as ever, although many lives were saved by the use of drugs, and HIV/AIDS was presenting a horrific challenge.

Health at the Dawn of the AIDS Era

By the early 1980s sub-Saharan African life expectancy was 48 years, having increased by seven years in the previous decade, and seeming to promise similar gains to come. This was not to be so, because of problems in funding the health system and the emergence of the AIDS epidemic. In contrast to most of Asia and North Africa, female child mortality was as low as that of males. There were significant mortality differentials by region (with mortality lowest in Southern Africa), ethnic group (even when neighbors), parental education (with mother's education being more important for child survival than father's education), by occupation (with farmers' death rates highest), and by residence (with urban health better). Mortality was highest in countries like Ethiopia and Mozambique where civil unrest and war had disorganized the health and other systems. It was also higher in the drought-prone savanna countries, but no higher than would be expected from their relatively low income and educational levels, which were in turn the product of impoverished agricultural resources. Drought still visited these lands regularly but evidence accumulated that, although it caused much distress and livestock loss, excess human mortality was less than might have been anticipated because of the scale of migration to better-off areas and towns.

Information on the nature of illness and the causes of death is still meager because so few people are seen by doctors or die in hospitals. By the 1980s the great epidemic diseases were largely under control. Campaigns, which mostly proved successful, aimed at eradicating onchocerciasis (river blindness), and some progress was being made against schistosomiasis (bilharziasis). Malaria, particularly its worst form, falciparum malaria, was almost universal, moderated only in the highest parts of East and Southern Africa by lower temperatures and in South Africa by a more temperate climate and successful eradication. A Gambian study revealed malaria to be the dominant cause of illness, except among children under 3 months of age, who were relatively free of it. Research in Tanzania showed that 31% of the sick were suffering from malaria, 13% respiratory infections and 7% diarrhea.

A major World Bank/Harvard University study (Murray and Lopez, 1997) of global mortality estimated that 65% of the region's mortality was still attributed to communicable, congenital, maternal, and nutritional causes (compared with 51% in India, 42% in all developing countries, and 6% in developed countries), 23% by non- communicable disease, mostly cardiovascular and cancer (compared with 40%

in India, 47% in all developing countries, and 86% in developed ones), and 12% by violence and accident (only a little higher than other areas). A World Bank survey (Feachem and Jamison, 1991) found that 47% of deaths were from infectious and parasitic causes (malaria and measles being particularly important), which, together with perinatal problems, accounted for nearly all child deaths, and 16% from circulatory disease and cancer (but their category of 'other,' including indefinable, was 23%). A longitudinal study in Machakos, Kenya (Muller and van Ginneken, 1991), an area where altitude renders malaria a minor complaint, ascribed 16% of deaths to respiratory infection, 13% to congenital factors, 11% to intestinal infections, 8% to measles, 7% to tuberculosis, 7% to other infectious and parasitic diseases, 4% to nutritional and metabolic causes, 4% to problems of the digestive system, 3% to malaria, 11% to diseases of the circulatory system and cancer, and 6% to violence and injuries, while 11% could not be determined. Hepatitis B also presents dangers. Maternal mortality has been estimated at 655 per 100 000 births, the world's highest level and 30 times that of Europe. This, together with deaths arising from miscarriages and abortion, translates, because African women still average six live births, into a lifetime chance for females of dying from maternity causes of about 5%. It is likely that the lifetime risk will fall substantially in the near future as the result of a fertility decline.

The AIDS Epidemic

HIV-2, perhaps the more ancient of the two human immunological retrovirus strains, is present in West Africa, Angola and Mozambique, but, because it is not a major cause of mortality, will not be discussed here. The HIV-1 /AIDS epidemic began in East Africa in the early 1980s, at much the same time as it appeared elsewhere. By the mid-1990s prevalence rates in Southern Africa were higher than they have ever been in East Africa. UNAIDS/WHO (1998) estimates for the end of 1997 indicate that 9.6 million Africans have already died of AIDS (82% of the world total) and a further 21 million are now infected (69% of the world total). More startlingly, there are 15 countries, constituting the 'Main AIDS Belt' and stretching from Ethiopia through East Africa to South Africa, which contain 4% of the world's population and half the world's HIV/AIDS. All of them have adult HIV prevalence rates of at least 9%, but the rate reaches 15% in Malawi and Mozambique, around 20% in Namibia and Swaziland, and 25% in Zimbabwe and Botswana. The latter levels imply more than a doubling of the death rate, with a lifetime expectation of dying of AIDS over 50%. United Nations population projections do not anticipate Zimbabwe regaining its 1985 life expectancy without a gap of 35 years, or Botswana with a smaller gap than 50 years. Sub-Saharan Africa's epidemic is almost entirely heterosexual in primary transmission, with the result that at least as many women as men are infected. Thus, although the region contains only 59% of the infected men in the world, it has 81% of infected women, and, because of higher birthrates, probably at least 85% of infected children. Thus, almost uniquely in the world, all parts of the community are affected. The AIDS epidemic is also catalyzing an increase in tuberculosis levels. There is growing evidence that HIV-positive women are likely to be rendered infertile or subfertile. Campaigns to contain the epidemic have been less intensive than the crisis demands, and largely ineffective.

The African Health System

Government hospitals are found chiefly in towns, with teaching or specialist referral hospitals in the capitals or other large cities. In most countries there are also missionary hospitals, often in rural areas. Nevertheless, most rural people depend on primary health services in the form of village health posts, clinics or dispensaries, and health centers. This system is developed to very different degrees across the region, and the health facilities often have insufficient drugs. Most have now moved to a 'user-pays' system, often characterized by declining attendances and by women losing their ability to take their children straight to the facilities without consulting male relatives (Orubuloye et al., 1991). Research has shown that most clients of health centers come from no further away than the village in which the center is located.

The system is supplemented by private pharmacies and medical stores. A Nigerian study showed that in rural areas the majority of drugs sold are malaria suppressants, worm syrups, and analgesics, although antibiotics are usually also in stock. Private doctors and nurses are becoming of increasing significance in most countries. Traditional practitioners remain important. They do not have an agreed-upon pharmacopeia as in various Asian medical systems, and their medicines are derived from animals as well as herbs. Many also identify evil forces and reveal how they can be nullified.

The great campaigns which eliminated smallpox and contained sleeping sickness, yellow fever, and cholera are largely things of the past, although watch is kept for outbreaks. Efforts continue to reduce the incidence of leprosy and tuberculosis, and to ensure that those people with malarial fever do not die. Immunization of children is now a major health weapon, and recent years have seen sustained attempts to control measles. Public health efforts continue to ensure safe drinking water and sanitation, but it is unlikely that the levels of safety are as high as respondents report to the international survey programs.

Trends in the Research Literature

More articles on the social and behavioral aspects of health are published in the journal *Social Science and Medicine* than anywhere else. In the last quarter of the twentieth century 865 of these papers were on sub-Saharan Africa. Their numbers rose rapidly at first from an annual average of nine during the late 1970s to 24 in the early 1980s and then reached a plateau at just under 50 per year. Many of the articles were derived from empirical studies of specific locations or diseases. The major topics were access to health services (132 papers), the interaction of traditional and modern health beliefs and services (75 papers), HIV/AIDS (68 papers, nearly all in the 1990s), maternal and child health (55 papers), the political economy of health (48 papers), and health economics (39 papers). Some trends were noticeable. The number of papers published on the interaction between traditional and modern health services declined after the 1980s,

those on the political economy of health peaked in the late 1980s as economic structural adjustment policies were applied, and HIV/AIDS papers mostly appeared in the 1990s, with no clear trend during the decade.

The Future

The immediate future is not reassuring. In contrast to the rest of the world, the regional life expectancy is stalled at under 50 years. Most sub-Saharan African countries are unable to do more than maintain their present public health systems. The impact of such systems depends on their level of use, which is largely determined by the population's ability to pay, and by their level of education, which raises the priority given to successful treatment and the skill with which it is administered. The fee-for-service principle is limiting the expansion of use of both the health and education systems. On the other hand, the likelihood of accessing the health system is probably increasing with the transition from subsistence to market agriculture. Fertility decline has now begun in a range of African countries. Smaller families will mean fewer women dying from maternal causes, and probably greater concentration on the education and health of children.

It is now likely that no country in mainland sub-Saharan Africa will, by the year 2000, have attained any of the three criteria established by the World Health Organization to certify the attainment of the 1978 Alma Ata Declaration of 'Good Health for All' by the year 2000: a life expectancy of at least 60 years, and a survival level of 95% of births to 1 year of age and 93% to 5 years of age. Indeed, most of East and Southern Africa will probably by that date be slipping further away from these criteria.

Editor's Note

The Ebola virus, rampant HIV infections, the emergence of multiply drug-resistant strains of tuberculosis, along with the traditional African morbidities (malaria, lung infections, diarrheal diseases, tetanus, meningitis, elephantiasis, leprosy, helminthiasis, and the panoply of STDs) has kept the health of the African population on the minds of health researchers around the world. Indeed, it is not unfair to say that African morbidity and mortality is its own subsection of the public health discipline. So the recent literature on African health and disease is vast (Giles-Vernick and Webb, 2013; Jamison et al., 2006; Crane, 2013; Cooper et al., 2013; Fassin, 2007; Amzat and Razum, 2014; Webb, 2014).

Abstract

African and African-American intellectuals long sought to counter primitivizing ideologies of their times by pointing to narratives of African state building. The real breakthrough in writing African history occurred as colonial rule was crumbling and the quest for a usable past – notably a usable *national* past – attracted young scholars in Africa and beyond. If the 1960s witnessed an emphasis on the particularity of African societies, disillusionment with Africa's present brought about a wider consideration of its past, especially the ways the slave trade and colonization constrained the continent's possibilities. Scholars attempt to document varied forms of imagination and communication, of networks and institutions, in different temporal and spatial frameworks.

The first task African historians had to accomplish was to show that African history actually existed. Scholars in Europe and North America had long treated Africa as the embodiment of the primitive and the traditional. In the early twentieth century, a more sophisticated version of anthropology began to treat Africa as a laboratory of social specificity, where forms of social organization could be compared as if each were bounded and timeless. As Africa's subordination to European powers came under increasing attack in the late 1940s, intellectuals inside and outside Africa began to argue that rethinking Africa's past was a necessary part of its future.

The idea of a usable past – specifically a usable national past – was African history's strength and its weakness in the 1960s. Asserting that history could be studied scientifically was part of a new politics of intellectual inquiry. Pioneering studies stressed the dynamism of precolonial societies; resistance to conquest was a harbinger of nationalist movements. But by the 1970s, a more complicated present was leading to a more complicated past, above all to new ways of thinking about Africa's relationship to the rest of the world and the implications of this relationship for historical writing. Yet the time frame for considering the emergence of African history needs to be pushed back even further, and its spatial dimension – the definition of Africa, the relationship of its constituent social and political units, and the significance of the continent to Africans in the Americas – need examination as well. The period after independence is just beginning to be the focus of historical inquiry.

Africa and the World

Africa was in part an invention of its diaspora, a unit that became of world-historical significance because slave traders – from the sixteenth century – defined it as a place where one could legitimately develop commerce in human beings. Over time, enslaved Africans and their descendants in the Americas began to appreciate the commonality of their fate and many looked to 'Africa' as an almost mythic symbol of their being something more than chattel. Certain nineteenth century African-American religious leaders looked toward 'Africa' and 'Ethiopia' (although few slaves came from that kingdom), and through such language asserted Africans' important place in a universal history – in the unfolding of Christian civilization. As some people of African descent returned to the continent in the nineteenth century – repatriated ex-slaves to the British colony of Sierra Leone, Brazilian traders in the Bight of Benin or Angola – some saw themselves as part of broad, transatlantic 'nations', sharing ancestry and culture but needing Christianity to link a torn-apart past to a reintegrated future (Matory, 1999; Hawthorne, 2010; Peel, 2003; Ferreira, 2012).

By the late nineteenth century, Africans from coastal societies – Christian, Western educated, but integrated into regional social organizations – began to write about their own regions in terms that linked different historical sensibilities. Africanus Horton (1868), Edward Wilmot Blyden (1887), and J. E. Casely-Hayford (1903) countered the primitivizing ideologies of the eras of the slave trade and colonization by describing African societies as complex entities whose traditions of origin defined commonality, whose ideas about kingship and social hierarchy defined political order, and whose interest in commerce with the outside world, in Christianity and Islam, and in Western education marked an open, adaptable attitude to interaction. Africans, they thought, had much to learn from Muslims and Christians, but they brought their own ideas of statecraft and of economic organization to the encounter as well.

The period of escalating European exploration and eventual conquest (from the 1870s to 1910s) brought to African contradictory regards. Some explorers encountered powerful kingdoms whose power they had to respect; others recognized in the impressive mosques of the West African desert edge or the East African coast a history of a long encounter of Africans with the outside world; but many chose to see an unchanging landscape of different peoples ensconced in their particular cultures. The culturally mixed inhabitants of West Africa coastal region were marginalized by colonization; the worldwide connections of African Muslims were played down in favor of their 'tribal' characteristics.

After some efforts toward remaking African societies in a European image – the 'civilizing mission' – colonial regimes began to hitch their legitimacy to the chiefs whose authority toward their subjects colonial rulers needed. With that, the idea of 'tradition' as the essential quality of African life acquired a new salience in colonial ideologies. Colonial regimes – and scholars and intellectuals of that era – were interested in

 http://dx.doi.org/10.1016/B978-0-08-097086-8.10116-3

'customary law', in 'folklore', and in 'primitive art'. The growth of African ethnography in the 1920s brought to the continent foreign scholars curious about the diversity of social forms and sympathetic to victims of colonial oppression, but their emphasis on the bounded integrity of each African 'society' was for the most part ahistorical (Conklin, 1997; Sibeud, 2002).

A New Past for a New Future

Even within the ethnic cages of colonial polities, consciousness of the past did not necessarily remain static. Some early mission converts used their literacy in French or English to record genealogies and traditions of 'their' people – using the legitimacy of 'European' writing to articulate indigenous views of the past and to emphasize the integrity of local society (Peterson, 2004). Such histories were sometimes invoked to make claims for collective representation in state-sanctioned councils. Activists linked to international political organizations – pan-Africanist, communist, or otherwise – saw Africa as a once-dynamic continent severely damaged by an oppression they shared with people of color throughout the world, a situation which required liberation movements on a global scale (DuBois, 1946).

The burst of interest in African history after World War II thus has a deeper context. The break, however, was fundamental. In the aftermath of a devastating war against Naziism, European states needed simultaneously to justify their rule over African peoples and to intensify their use of African resources. The challenges to colonial legitimacy and control – from within and outside African colonies – and the increased intrusiveness of regimes into African social and economic life has made this a fascinating period for historical investigation (Cooper, 1996). Even at the time, scholars and intellectuals wondered whether the conception of bounded and static units made sense of the Africa they were observing. Although a few anthropologists had seen in the 1930s that migration, for example, was redefining the nature of social connections, by the 1950s, population movement, cross-cultural interaction, and cultural adaptation demanded scholarly analysis. Meanwhile, the anthropologist Melville Herskovits (1944, 1958) was asking what Africans' experience of governing indigenous kingdoms had to offer to Africa's political future and he was pointing to the influence, via the long history of the slave trade, of African cultures on the New World.

That African polities could be a model for the future was not a possibility for most African political elites – and almost all social scientists – wanted to think about; the 1950s witnessed the escalation of claims from African social movements to be considered part of the 'modern' world and to enjoy the possibilities it entailed, irrespective of race or a past of colonization or enslavement. Social scientists took more interest in where history was supposed to end – 'modernity' – than where people had been. Even Georges Balandier's (1951) insightful analysis of the 'colonial situation' had limited echoes in subsequent years.

Academic historians, the professional custodians of the past, were part of the postwar political and intellectual ferment. The first African PhD in history K.O. Dike of Nigeria was trained by historians of imperial expansion, but he told a different sort of story, one of the interactions among traders, rulers, and warriors, both African and European, in the Niger Delta, and of the adaptation of African social institutions to new forms of competition in the nineteenth century. Dike (1956, based on a 1949 dissertation) insisted that oral sources could be used alongside written ones, although most of his own work was archival. At one level, his work staked itself on using the canonical methods of European history to a different end; at another, his insistence that the locus of history could be found in Africa itself – that interaction was more important than transmission – was a charter for nationalist history.

The next generation of European-trained African historians went further in this direction, and many stressed explicitly that the preconquest past was a precedent for the postindependence future, showing how Africans had brought diverse populations into larger political units, how African initiative in agriculture and commerce had linked ecologically distinct regions with each other and with the outside world, how indigenous religious leaders had built networks that transcended ethnic frontiers, and how Africans had adapted Islam to particular political and cultural purposes (Ranger, 1968).

The quest for a usable past was a strength because it attracted a younger generation of Africans to believe that they could combine international scholarship with a sense of the past they had learned in their own communities and because it allowed Americans and Europeans to come to grips with the way in which the end of colonial empires had forced a reordering of intellectual categories. It was also a weakness because the political context privileged 'state building' over the diverse strategies of women and men, traders and religious figures to live their lives in different ways, and this both diminished a varied past and ratified an increasingly authoritarian present within the new African states. The only aspect of colonial history that fitted the bill was 'resistance'; indeed, some African historians saw the 'colonial episode' as a short and not particularly important interval between an autonomous past and an independent future. A consequence of the new historiography, whatever its limitations, was a heightened interest in methodology, to solve the problem of how to reconstruct historical patterns with a paucity of written documentation, much of that from visitors and conquerors. Jan Vansina (1965) helped to develop rigorous criteria for analyzing oral texts with the same critical eye as employed on written ones, and other scholars explored the use of linguistic and archeological material to chart the movements of people, the evolution of material culture, and the spatial configuration of state building.

African historical scholarship was vibrant in the 1960s and 1970s, and the core of the action was in Africa. Every nation had to have a university, every university a history department. Associations and journals were founded; international congresses were held; and UNESCO brought together African authors to write a comprehensive history of the continent (UNESCO, 1981–93).

Reconnecting Africa and the World

Since the 1970s, African historians have become increasingly conscious of the different ways of rethinking the relationship of

Africa and the rest of the world. They no longer had to prove that Africa had a history. The mounting evidence that decolonization did not free Africa from its problematic relationship to the world economy raised questions about pasts before and during colonization. Why African polities became caught up in the Atlantic slave trade, how the African presence in the Americas contributed to European wealth, and how African societies coped with unequal trade and unequal politics became topics of increasing interest (Rodney, 1972). French Marxist anthropologists (Meillassoux, 1975) argued that such institutions as kinship systems were not so much the product of a peculiarly African culture but of the logic of reproduction of agricultural societies, and they went from there to posit that the resulting modes of production interacted in particular ways with the expanding capitalist system. Other scholars saw that the question appeared differently if instead of asking how a 'society' responded to European traders or rulers one asked how ruling elites reacted. They showed that the strength of internal social groups made rulers look to the manipulation of external relations for power and wealth, and that this made African kingdoms and chiefdoms especially open to external relationships, most disastrously those of the slave trade and later of colonial economies (Peel, 1983). The most recent work on the slave trade emphasizes the intersection of different trading networks – those coming out of African polities seeking external resources with those coming out of Europe that developed to meet the voracious demand for slave labor in the plantations of the Americas from the sixteenth century onward (Green, 2012; Nwokeji, 2010; Heywood and Thornton, 2007).

Historical research allowed not just the use of 'informants' to gain information, but the juxtaposition of different kinds of historical sensibilities and the elucidation of how thinking about the past affects and is affected by political processes in the present (Cohen, 1994; White et al., 2001). Oral history revealed different lines of cleavage within African societies, including gender, age, and status. It described not the actions of fixed social groups against each other, but the flexibility of social arrangements, such as the tendency of people detached from kinship groups – through war or efforts to escape patriarchal authority – to form important but unstable groups of clients of 'big men'. Both oral sources and more nuanced reading of documents reopened the colonial era to historical investigation, not as a history of what white people did for or to Africans but as a dynamic process, in which the limited power of colonizing regimes left numerous fissures where women tried to establish autonomy even as male elders tried to contain it, where labor migrants developed networks linking distant regions, where Christians built independent churches and cults, and where cash-crop producers used their incomes to enhance their kinship groups and chieftaincies. Such histories stand alongside those of expropriation of resources of segregation and discrimination against the most 'Westernized' of Africans, of arbitrary authority, and daily oppression under colonial regimes, in their late, 'reformist' phases as well as brutal early ones. South Africa's path to a racialized form of capitalism – with most Africans deprived of access to land and forced to work part of their lives while being treated as members of 'tribes' – led to a quite distinct economic structure while carrying invidious distinction making (among Africans and between Africans and whites) to an extreme. South Africa's deepening of its form of white domination after 1948, just as Britain and France were staking their legitimacy on development and partial acknowledgment of African political voice, marked a parting of the ways. In the end – but only slowly and painfully – the defense of white power in Portuguese, Africa, Rhodesia, and South Africa proved impossible as independent states offered models and sanctuaries for rebels and as global norms were transformed.

Studying African history has offered the possibility of thinking about 'world' histories in a different way. Rather than seeing Africa as a peculiar place that somehow lacks what made other regions develop more rapidly, one can ask what is particular about each region of the world and what, in the process of interaction, produced inequalities of wealth and power. African historians have been in dialogue with historians of Latin America over economic history and with historians of India over the analysis of colonialism. World history can no longer be seen as a single narrative, but this recognition leaves in place the more difficult question of how is one then to analyze large-scale historical processes. The challenge is to chart the multiple pathways without losing sight of the development of highly unequal political and economic relations on a global scale. Recent work in economic history has cautioned against generalizing about African backwardness, instead emphasizing the unevenness of patterns of economic growth. Africa has experienced growth spurts and periods of retrogression – the 1980s prominent among the latter – and different parts of the continent have followed different trajectories (Jerven, 2010). Such a historical change requires analysis that does not reify 'Africa', or 'Europe', but focuses on complex relationships over 200 years.

The Peculiarities of Disciplinary Divisions of Labor

In the 1930s, Africa not only had no history; it held no interest for political scientists or sociologists either, and for economists only in the sense the colonial economies had spawned 'modern' sectors with certain measurable characteristics. Africa was the domain of anthropologists, the custodians of human particularity, while what was putatively 'European' was assimilated to the universal, and that was where social science found its glory. The dramatic challenges to European power in the 1940s and 1950s shook up this division of labor (Pletsch, 1981). The idea of modernization was espoused within colonial bureaucracies before 'modernization theory' – in the style of the Committee on Comparative Politics of the Social Science Research Council – came into vogue. It allowed officials to think that even if African colonies became independent, they would follow a road charted out to them by the early developers (Latham, 2000). However much modernization reinscribed global hierarchy, eurocentrism, and teleology, it offered African intellectuals and policy-makers a chance to position themselves as mediators between a perceived Euro–American modernity and diverse African particularities; it gave a language to leaders with which to ask industrial countries for the resources they needed to 'develop' and it allowed outsiders to see themselves as forging a world in which people of all races could advance.

American and European political scientists and sociologists flocked for a time to Africa – and their standards of empirical research deserve some of the credit for deflating modernization theory. But after that time, the interest of political scientists, sociologists, and economists in Africa has waned. Anthropologists remain the custodians of African particularity, but now this embraces the complexities of innovation and interaction more than unchanging specificities. Historians, from the 1950s, were the new element in the division of labor, and their work, despite temptations to the contrary, can offer a vision of Africa that stresses change – economic, political, social, and cultural – without confining it to a predetermined route.

Some historians have their version of the modernizing vision. The narrative of African state building from the empire of Sundiata to the empire of Shaka was indeed a selective reading that tied progress to the state. Even the 'underdevelopment' school of the 1970s is as a variant of modernizing themes, for its emphasis on how over the long-term European exploitation retarded growth and transformation in African economies presumes a global narrative of capitalist development which Africa is then held to fall *under*. That Europe's oppression, not Africa's backwardness, is held culpable does not negate the inattention to the myriad innovations, struggles, and changes that have occurred within parts of Africa, the importance of regional, not just overseas, mechanisms of exchange and communication, and the ways in which the actions of Africans limited the actions of Europeans, whatever the latters' intentions (Cooper et al., 1993). Much recent social and economic history bounced off the arguments of the underdevelopment school to develop more varied and more interactive views of change in various periods of African history, including those when European power was seemingly at its height (Berry, 1993).

Multiple Perspectives on a Varied Continent

If Africa is neither a homogeneous space reduced into abject poverty by imperialism nor a series of autonomous societies with their own internal logics, getting a grip on units of analysis is not simple. Rather than take present-day ethnicity as a starting point, some scholars have used concepts of region, of network, and of patron–client relations to see how people in the nineteenth and twentieth centuries constituted actual patterns of relationships, which only sometimes crystallized into groups that maintained boundaries (Ambler, 1988; Glassman, 1995; Barry, 1998). Others have emphasized the long-term interconnectedness of different parts of Africa and with other parts of the world: on trade routes and Islamic networks crossing the Sahara (Lydon, 2009), on further connections to Egypt and Arabia, on efforts to build Islamic states within sub-Saharan Africa, and on the ways in which Islamic networks both accommodated to and challenge colonial regimes after the conquest (Robinson, 2000; Hanretta, 2009). Others have examined how African-American missionaries from the 1890s influenced Christianity in South Africa, and how in the 1920s African ports became nodal points in the spread of Garveyite movements across the Atlantic to large parts of Africa (Campbell, 1995). We have learned not only how European states used various coercive means to push Africans – especially younger males – into periods of wage labor away from home, but how Africans themselves developed migratory networks and social institutions to make life in cities, mines, or distant farms more palatable (Manchuelle, 1997). That Africans educated at missions sometimes fought for more voice or control of churches or sought to forge their own social institutions and norms that reflected what they brought to the missionary encounter has become a focus of inquiry (McKittrick, 2003).

Having for some time now moved beyond the need to recuperate a singular African voice, historians have devoted attention to questions of gender, generation, and class – examining both tensions within African societies and connections across social cleavages. Some have argued that colonial rule enforced a view of male and female roles more rigid than had been the case before colonization, but in any case research has revealed struggles – before, during, and after the colonial period – over questions of the norms governing the roles of men and women, young and old (Thomas, 2003). And if slavery, pawnship, manumission, and emancipation have been themes of historical scholarship for some time, more attention is being paid to the ways in which unequal relationships are pushed and pulled from both above and below (Glassman, 1995).

If we circle back to where we began – how national independence shaped the quest for a usable past – we find some historians turning away from their supposed role as organic intellectuals of the nation to point to forms of political affinity that are both sub- and supranational. The politics of the 1940s and 1950s turns out to be more complicated than a quest for the nation in the face of an obdurate colonialism. If some Asante leaders made 'national' claims in the same term as the movement of Kwame Nkrumah, those claims were for a different nation – a region of Ghana. Almost all leaders of French Africa in the decade after World War II sought to make French citizenship into a meaningful category and to transform colonial empire into a federation or confederation of equal states, including France (Allman, 1993; Cooper, 2014). Nor were colonial regimes fixed targets. In fact, it was their attempt to regain legitimacy and efficiency that set the stage for an escalation of claim making by African political and social movements that colonial regimes, in the end, could not contain at an acceptable cost.

If the nation-state was not necessarily the aim of political movements in the 1950s, it was what they could get, and the new rulers of Africa largely erased the complexities of postwar political history in order to situate themselves as fathers of the nation. But the quest to complement 'flag independence' with projects of national economic development and forging a national culture ran into the problem that elites did not necessarily have the resources to make citizens see the rewards of political participation. Some citizens, particularly youth, were caught between their own desire to participate in a national culture and their interest in transnational cultural tendencies and radical politics that governing elites found threatening (Ivaska, 2011). Scholars are uncovering more diverse and richer forms of imagination and communication

among different parts of African populations than opposition of colonizer and colonized, African and European, white and black would suggest (White, 2000).

Conclusion

The Senegalese novelist and filmmaker Ousmanne Sembene accused historians of being 'chronophages' – eaters of time. They impose, he insists, a one-dimensional, progressive view of time on the unruliness of people's experience. Yet the idea that other notions of past give a more varied picture than professional history depends on aggregating different visions of the past – a quintessentially 'academic' operation. The griot or the lineage elder may also recount the past to serve narrow, presentist concerns. Historical scholarship has complicated unilinear narratives as well as imposed them.

The doing of history introduces a tension between a historian's imagination rooted in the present and the fragments of the past that appear in all their elusive vigor, in interviews, letters, newspaper articles, and court records. The data of history are not created neutral or equal: archives preserve certain documents but not others, and the tellers of oral tradition remember some narratives and forget others.

African history has offered a glorious national past that points to a national future, and it has offered an ethnicized past projected backward in time. But history can also be read as process, choice, contingency, and explanation. Since World War II, historical scholarship has provided a sense of the possibilities which mobilization can open up – and an awareness of the constraints that have made and make it so difficult for African states and societies to make their way in the world.

Abstract

Humans are an important component of the biophysical environment in Africa, interacting with its resources through prisms of knowledge structures to harness and manage resources sustainably. A review of the human sphere (e.g., population and migration, land and land use, agriculture, and food security) and the ecosphere (e.g., environmental change, biodiversity, water, and coastal resources) is undertaken. The review suggests an environment which is generally degraded, and blamed on biophysical processes and policy failures. Mainstreaming policies and decision-support systems of different sectors and development processes would help reduce conflicts in resource use toward maintaining the integrity of Africa's environment.

Introduction

Africa has an environment which is endowed with a wealth of natural resources, including minerals, land, biological diversity, wildlife, forests, fisheries, and water, and shaped by various factors that may be classified as human or anthropogenic, and natural. The factors include, but are not limited to, population growth, widespread land degradation and desertification, overfishing, deforestation, loss of biodiversity and loss of arable and grazing land, pollution and deteriorating air and water quality, worsening sanitation, declining soil productivity, and depletion of freshwater resources (UNEP, 2003). These issues have far-fetching implications for human welfare, sustainable development, resilient livelihoods, and efforts to eradicate poverty (WRI, 2005). In Africa, society perceives and interprets its biophysical surroundings through its own way of life and culture, within which the physical environment affects humans. The relationship between humans and the environment has often produced two schools of thought: natural against artificial, human or cultural, based on arguments that the activities of humans are strongly controlled or conditioned or even determined by the biophysical environment (Farina and Napoletano, 2010).

Through processes of adaptation, cultural appraisal, innovation, and experimentation, humans are able to influence their environment. For example, in Africa, people shape much of 'the wild' and many species have been carefully nurtured by people, albeit less intensively than those cultivated (Bell, 1995). Hence the surface of the earth as modified by human action represents a cultural landscape defined as geographic areas in which the relationships between human activity and the environment have created ecological, socioeconomic, and cultural patterns and feedback mechanisms that govern the presence, distribution, and abundance of various life forms (Farina and Napoletano, 2010; Taylor, 2002). A review of Africa's environment as a cultural landscape is pursued from two compartments, namely the human sphere and the ecosphere, toward understanding how these are shaping the African environment.

The Human Sphere

Population, Migration, and the Environment Nexus

Africa's annual population growth rate is estimated at 2.3% (UNFPA, 2011), rapidly growing than in other regions of the world although with known consequences for adaptation and sustainable development efforts. As home to an estimated 900 million people, it is projected to grow to 1.2 billion by 2025 and to 2 billion by 2050. Sub-Saharan African countries would be growing more than any other continent (UNPD, 2011). Over 46% of the 2.4 billion people who are projected to be added to the world by 2050 will come from sub-Saharan Africa, contributing 77% of the total increase in global population by 2100 (UNPD, 2011). The growing population would place increasing strains on all aspects of the environment, thus calling for meshing population and economic growth with environmental protection. Urban areas will experience most of the pressures in the coming years, resulting in pressure on urban managers to expand existing services particularly to the poor and those remote from such services. It is expected that there would be gradual but increased displacement and migration of human population as a result of environmental change (e.g., overpopulation, overfishing, land degradation, deforestation, climate change, land use, and land cover change). Movement of people within the continent has dominated cross-border migration (Dovie et al., 2012).

Traditional arguments portray migration and migrants as threats to human security, survival, and development, while the development community argues that human mobility is a development tool and likely to contribute immensely to development than not (Landau and Vigneswaran, 2007). Land use and land cover changes are major outcomes of migration in Africa, as migrants often converge in fragile environments to adopt means to diversify or self-insure risk involving collective decision-making. Such decisions can also contribute to ensuring that usage of environmental resources is sustainable. Migrant practices such as illegal mining have polluted several rivers, enhanced deforestation, displaced communities and farms, and augmented floods, and led to overfishing and

a source of conflicts. Cross-border movement from land degradation has created basic natural resource scarcity. Remittances remain a significant outcome of migration, and therefore are important social safety nets to cushion the poor and offsetting additional burden on environmental resources (Dovie et al., 2012). The direct spending of remittances by families contributes to minimizing poverty outcomes and environmental degradation. Generally, it is expected that the high human mobility in Africa would result in rapid social and economic change with tremendous effects on the ecologically vulnerable or fragile biophysical environments (Dovie et al., 2012). Changes in rainfall patterns and stream flow will have a direct impact on human settlements, so many of which are already unable to provide reliable, affordable services.

Land and Land Use

Approximately 22% of the total land area of Africa is under forest, 43% is characterized as extreme deserts, and 57% is vulnerable to desertification. While 21% of the total land area is suitable for cultivation, it is estimated that some 500 million hectares of land in Africa has been lost to soil degradation of which 65% could be described as agricultural land. Overgrazing is the leading cause of land degradation in Africa, followed by crop production-related activities and vegetation removal (UNEP, 2003). Some 202 million hectares of land can be cultivated and put to various uses in Africa, thus representing nearly half of the world's usable uncultivated land (Byamugisha, 2013). Human activities (land uses) that directly affect the environment constitute proximate sources of change, connecting the cultural landscape and human purpose or intent which reflect human goals. Agricultural expansion, wood extraction, and infrastructure extension are the leading causes of the change underlain by economic factors, policy, and institutional, technological, cultural, and demographic factors (Geist and Lambin, 2002). It is estimated that 79% of the total traditional energy consumed in developing countries is fuelwood, with over 90% dependence in sub-Saharan Africa (UNEP, 2003).

The unfamiliarity and haphazard appearance of domestic gardens in Africa is often overlooked for the rich complexity of these production systems. Forests and other vegetation formations that extend from the immediate neighborhood of settlements have been assumed to be self-regulating wastelands and subjected to abuse (Bell, 1995). However, because land is central to the existence of humans as a source of major ecosystem services such as food, fiber, and medicines, the sustainable management of land can enhance the health of people through increased access to a wider range of ecosystem services (UNEP, 2013). Yet inappropriate land use practices, resulting in loss of vegetation cover, excessive use of chemical pesticides and fertilizers, salinization, contamination by heavy metals, and soil depletion adversely affect land productivity, subsequently leading to land degradation which impacts negatively on food and nutrition security (UNEP, 2003). Yield losses from soil erosion in sub-Saharan Africa are between 2% and 40%, and some changes in land use are known to alter the ecology of human diseases, making people more vulnerable to infections (Collins, 2001). The Africa Health Strategy 2007–15 (AU – CAMH, 2007) emphasized that environmental factors and degradation are not sufficiently addressed in health, which is adding to disease burden factors in Africa and should be prioritized in health planning on the continent. The mounting costs of floods in Africa are partly due to land use changes that push populations and assets into vulnerable areas. Therefore urbanization and land use planning can also be drivers of water impacts on society and vice versa.

Resource Use, Indigenous Knowledge, and Livelihoods

Human societies have for generations interacted with their environments mediated through basic knowledge structures. One of the results of this interaction is the immense genetic diversity within traditional farming systems today. In Africa, kinship ties for instance form the basis for local level decision-making on aspects of livelihoods and resource management, dictated by knowledge and societal norms (Larson, 1998). This knowledge, which is often indigenous in nature or in origin, is generally poorly documented, leading to fears that the long experiences possessed by many traditional and local communities in the use and management of the cultural landscape such as conservation of natural resources would be lost. For centuries, rural peoples have relied on nature for their livelihoods. Farmers have managed genetic resources for as long as they have cultivated crops, and the historical importance of local people as having the knowledge and skill to manage biodiversity through their biocultural diversity is crucial (Moore et al., 2002). Historically, some of the knowledge is administered through cultural factors such as taboos that placed limitations on resource use. Local and indigenous groups could therefore provide much of the intellectual raw material for the sustainable harvesting and management of natural resources.

Thus in Africa, key livelihoods, which comprise capabilities, assets (stores, resources, claims, and access), and activities required for a means of living (Carney et al., 1999), are a product of knowledge systems, resource tenure, and use. Livelihoods are therefore seen to consist of a range of on-farm and off-farm activities that together provide a variety of procurement strategies for food, cash, and in-kind income. It could also be informal or formal, and comprising entitlements and capabilities. As a result, it has been argued that livelihoods and natural resource use are inextricably linked in Africa, often quite diverse and engaging capabilities, skills, and know-how to offset risks that lead to livelihood security (Dovie et al., 2005). It includes adequate access to food, potable water, health facilities, educational opportunities, housing and time for community participation, and social integration. Natural capital comprising land, water, air, rivers, lagoons, oceans, and forests, and wetlands have been major sources of drivers of livelihoods in Africa, providing short-term coping mechanisms in response to shocks and stresses. They also have become adaptive strategies, including the long-term changes and adjustments people make in their livelihood systems based on various knowledge systems in order to respond to difficult circumstances.

Agriculture and Food Security

The importance of agriculture to provide food security comes in two ways, firstly producing the food people eat, and secondly

(perhaps even more important) providing the primary source of livelihood for 36% of the world's total workforce. In sub-Saharan Africa, two-thirds of the working population still makes their living from agriculture (ILO, 2007). Sub-Saharan Africa and Asia have the most share of food insecurity represented by almost 90% of the undernourished people in the world. Almost 870 million people were described as chronically undernourished in 2010–12, where the vast majority live in developing countries having about 850 million people estimated to be undernourished (FAO, WFP, IFAD, 2012). Agriculture is the largest contributor to Gross Domestic Product (GDP) in Africa as the biggest source of foreign exchange, accounting for about 40% of the continent's foreign currency earnings, and the main generator of savings and tax revenues. About two-thirds of manufacturing value-added is based on agricultural raw materials. Agriculture remains crucial for pro-poor economic growth in most African countries as rural areas support 70–80% of the total population. This means that improvements in agricultural performance have the potential to increase rural incomes for large numbers of people to lift them out of poverty and food insecurity. In spite of efforts in place to reverse the undernourished trend in sub-Saharan Africa, an estimated 25% of the African population still remains undernourished, as average protein supply in Africa is estimated as 20% lower than the world's average (FAO, 2011). Yet, climate change is expected to increase the number of undernourished people by between 35 and 170 million people in 2080, depending on projected development paths (Shah et al., 2008). Overall, approximately 40% of sub-Saharan Africa countries will be at risk of significant declines in crop and pasture production due to climate change (Shah et al., 2008).

Almost three decades ago, it was argued that several years of focusing on commodity crops across the globe had not ensured food and livelihood security for the world's poor, and that the focus on commodity-based agriculture threatened millions of people mostly in the developing world (Bell, 1995). It was shown that official agricultural development policy and research were dominated by global scenarios from the developed world, as a result interrupting the survival strategies of resource-poor regions including Africa. As such, the policy overlooked the role of agriculture within the wider portfolio of household livelihood strategies. Thus, agriculture and food production were seen as independent of the broader landscape rather than a strong connection with the wild through agro-ecosystems to domesticated landscapes and homestead gardens in sub-Saharan Africa, and that, inaccurate estimates of food insecurity still persist in Africa (UNDP, 2003). Several models for implementing food systems represent global scenarios and do not elicit the real local and national issues. Therefore, none of the variety of approaches provided definite analytical frameworks that are specifically designed to establish the implications of differences in the sociopolitical economy that influence or are influenced by food systems in local, rural landscapes in Africa. The global scenarios failed to

- account for small and micro-scale activities, subsistence production, and products without formal markets,
- recognize the impacts of social, economic, and demographic heterogeneity, and
- account for the effects and impacts of global environmental change, thus perpetually depriving the African continent of appropriately sustainable food security strategies.

The Ecosphere

Global Environmental Change and Climate Change

Changes in the environment are a process comprising land use and land cover changes, land degradation, desertification, overgrazing, overfishing, population growth, loss of biological resources, deforestation, greenhouse gas emissions, and atmospheric pollution, among others. Of these, atmospheric pollution has come under intense scrutiny in Africa for its implications for climate variability, climate change, and air quality although Africa's contribution to the global pool of greenhouse gas emissions is still relatively low. It is estimated that Africa contributed to only 3.57% of the world's total carbon dioxide emissions in 1988, yet remains the more vulnerable continent to the impacts of climate change (IPCC, 2007; UNEP, 2003). Climate change is attributed to both natural and human-imposed activities mainly through over-consumption of the earth's resources. The Fourth Assessment of the Inter-Governmental Panel on Climate Change (IPCC) reveals that Africa is warming faster than the global average and that it is likely to warm by an average 3–4 °C this century. Extreme weather events such as droughts and floods are also projected to be more frequent (**Figure 1**), intense, or severe with dire consequences for human life and health (IPCC, 2007).

In Africa, impacts of climate change are most felt as a result of widespread poverty, recurrent droughts, inequitable land distribution, and overdependence on rain-fed agriculture. Both climatic and socioeconomic stress shape the processes influencing local vulnerability to climate variation and change which are inherently dynamic, yet the socioeconomic context is seldom explicitly considered, either in local assessments of vulnerability to climate change or in local climate adaptation strategies (IPCC, 2007). Weak planning taking the form of reactive and sector-based responses has been attributed to improper reflection of stresses and the capacity to adapt to change. The high dependence of large populations on climate-sensitive natural resource sectors has increased Africa's vulnerability. Changes in weather conditions ultimately constitute climate variability which adversely impacts agriculture, often translating into income and food insecurity for least resilient communities (UNEP, 2013). Adaptation to climate change is complicated by limited economic diversification, poorly resourced governments and lead agencies, and the virtual absence of insurance cover for climate-sensitive investments such as agriculture. Thus if agricultural production in the low-income developing countries of Africa is adversely affected by global environmental change (e.g., climate change), the livelihoods of large numbers of the rural poor and the vulnerable will be put at risk and their vulnerability to food insecurity increased.

The Interdepartmental Working Group on Climate Change of the United Nations Food and Agricultural Organization estimates that Africa would face a 2–9% decrease of GDP from agriculture, attributed to climate change (FAO, 2007). The food

Figure 1 Trends of some extreme weather events associated with climate change. Source: UNEP, 2010. The Fourth Global Environment Outlook: Environment for Development, UNEP-WCMC. UNEP, Nairobi.

security implications of changes in agricultural production patterns and performance as a result of changes in rainfall patterns due to the overreliance on rain-fed agriculture on the African continent are of two kinds:

- First, impacts on the production of food will affect food supply while higher yields in temperate regions would offset lower yields in tropical regions. However, limited financial capacity to trade in many low-income countries and high dependence on own production to cover deficits in food production may not be possible to offset declines in local supply. The outcome would be the increased dependence on food aid.
- Second, the impacts on all forms of agricultural production will affect livelihoods and access to food and that subsistence agriculture in Africa risk having their security undermined, together with the food system.

Human settlements would be affected by changes in rainfall patterns and stream flow, so many of which are already under stress and experiencing shortfalls in the delivery of services. While climate change will impact the capacity to supply potable water, it will also reduce the capacity to dispose of wastes from large urban communities and accompanied by increased costs of appropriate infrastructure and logistics to manage such wastes (Sadoff and Muller, 2009). Groundwater recharge was forecast to decrease by the 2050s, and by more than 70% in Southwestern Africa. The costs of adapting to existing urban water infrastructure in Africa have been estimated at between US$ 1050 million and US$ 2650 million annually (Muller, 2007).

Biodiversity

The cultural landscape created biotic niches that maintain precise relationships with biodiversity and without this diversity the ability to adapt to changing needs and conditions of society and biodiversity would be lost. Africa has a large heritage of biodiversity, forming the basis of the region's natural wealth and development and hosting six of the world's 25 biodiversity hotspots. These resources also have global importance for the world's climate and for the development of agricultural or industrial activities. The region has more than 50 000 known plant species, 1500 species of birds, and 1000 mammals (UNEP, 2003). Africa's rich and varied biological diversity has considerable potential to enhance the productivity of other sectors, contributing immensely to attaining the Millennium Development Goals (MDGs). Africa's ecosystems are a host of a variety of fruits, vegetables, honey, spices, oils, bush meat, fish, edible worms, and mushrooms, contributing to food security on the continent and largely constituting the bulk of non-timber forest products (Dovie et al., 2005).

Recent reports (e.g., the *Africa Environment Outlook*) confirm that the wealth of Africa's biodiversity is being rapidly lost from uncontrolled exploitation and fragmentation of natural habitats largely attributable to rapid population growth and expanded agriculture. Increasing rates of deforestation, overgrazing, soil erosion, and desertification threaten biodiversity and the accompanying benefits to both the environment and humanity (UNEP, 2013). Increased dependence on narrow-range species, overharvesting, and climate change also contribute to ecosystem degradation and biodiversity loss and destabilizing ecosystem processes such as the predator–prey relationships that may create favorable conditions for disease outbreak (UNEP, 2013). Gitay et al. (2002) projected that climate change will halve Africa's biodiversity, affecting individual organisms, populations, species distributions, and ecosystem composition and function. This would be direct (e.g., through increases in temperature and changes in precipitation and in the case of marine and coastal ecosystems also changes in sea level and storm surges) and indirect (e.g., through climate changing the intensity and frequency of disturbances such as wildfires). Thus, significant declines in the

provision of wild foods by a variety of ecosystems, and further impacts can be expected as the world climate continues to change as it is predicted that 81–97% of the suitable habitats will decrease in size or shift owing to climate change. By 2085, between 25% and 42% of the species' habitats are expected to be lost altogether.

The dependence of human populations on ecosystem resources in Africa is well documented, harboring rich areas of important biodiversity including some of the richest tropical rain forests (e.g., the Congo). For example, Dovie et al. (2005) observed in a study of ecosystem resources (i.e., natural resources and agrodiversity including farming) that in the absence of jobs and confronted with high migrant labor, households with open access to natural resources derived more benefits from land-based livelihoods than cash income streams (i.e., 57.5% as against 42.5%). African ecosystems therefore hold key importance for bioprospection even on commercial scales which are significant in terms of livelihoods yet they are not always reflected in market prices (Dovie et al., 2005; Lawes et al., 2004). Forest resources in Africa are therefore important to the livelihoods of many communities, and more specifically in Western, Central, and Eastern Africa where forest resources still abound. On average, forests account for 6% of GDP in Africa and leading the world statistics (UNEP, 2003).

Water Resources

Africa's water resources are characterized by extreme spatial and temporal variability culminating in only about 4% of its renewable freshwater resources being used (UNEP, 2003). Batisani and Yarnal (2010) observe that variations in internal renewable water resources owing to a range of natural and anthropogenic factors such as uneven distribution of rainfall across the continent, its unpredictability, and high evaporation losses tend to influence the natural variation. It is estimated that 25% of the population (approximately 200 million people) are faced with water stress, with more countries expected to experience high risks in the future (Ludi, 2009). This may, in turn, lead to increased food and water insecurity for at-risk populations, and undermining growth and development. Africa's estimated annual per capita water availability stood at 4008 m^3, compared to the global average of 6498 m^3 in 2008 (UNEP, 2010). Water scarcity is projected to increase from 47% in 2000 to 65% in 2025 (Bates et al., 2008). The African continent holds up to 660 000 km^3 estimated groundwater and more than 100 times the estimated annual renewable freshwater resources of the continent (MacDonald et al., 2012). The largest groundwater resources are located in the large sedimentary aquifers in parts of northern Africa and mostly Libya, Algeria, Egypt, and Sudan, which is crucial to relatively dry and arid areas. Of particular concern is the situation in North Africa which faced limitations in renewable freshwater decades ago, while struggling to meet its food requirements based on the available water resources. As one of the driest regions in the world, the region contains only 1% of the world's freshwater resources (Qadir et al., 2007).

The majority of the population of sub-Saharan Africa still lacks safe drinking water, accounting for nearly one-third of the global 884 million people who have no access (UNEP, 2010). By 2010, only 23 countries were on track to meeting the safe drinking water MDG target (**Figure 2**). Although the actual number of people using improved drinking water sources had increased by 11% relative to 1990, only 66% had access to safe water (WHO and UNICEF, 2012). The United Nations Development Programme warns that the progress in human development achieved over the last decade may be slowed down or even reversed by threats to water security from climate change. The impacts of climate change could, by 2080, increase the number of people facing water scarcity by 1.8 billion (UNDP, 2008), with Africa likely to take the bigger share. In some drier areas of sub-Saharan Africa, reductions in stream flow of more than 50% are confidently predicted and many perennial streams would become seasonal, having limited flow and others drying up permanently (Sadoff and Muller, 2009). With water as the major platform for adaptation, climate change could severely impact on human activities through water and food insecurity while bringing about permanent changes in ecosystems through disruption in ecosystem services. Thus a threatened water resource base provides conditions for the disruption in biophysical properties, and social networks and capital on the African continent, as livelihoods of many rural people depend on the vagaries of rainfall. Thus the progress made in social and economic welfare and gains over many years are at risk of being eroded within shorter time periods through water-related stresses. For transboundary water resource networks such as river basins, water supply challenges would have negative consequences for social relations such as conflicts and migration.

Rapid urbanization especially of cities and increasing industrialization, water use, and consumption would become greater and in the process increase competition among the various uses of both human and ecosystem origins. Water use is generally greater than the amount consumed because of conveyance and other inefficiencies such as return flows from agriculture of up to 20–40%. Water usage for agriculture is estimated at 88% contributed largely by 40–60% of the region's irrigation which is lost through seepage and evaporation (UNEP, 2003). Lack of adequate water storage is characteristic of many African countries especially those in arid regions and even where there is significant storage, as in Southern Africa (the Zambezi), the remoteness of settlements undermines water security unless extensive transport and distribution infrastructure is put in place, which would be very costly. This is similar to Eastern Africa's lakes where there is natural storage to store large volumes of water but not easily accessible to the communities that need this water most (Sadoff and Muller, 2009). Problems on access and use of water resources should also be blamed on political, social, and economic factors because they fail to consider the influences of other sectors of the environment such as forestry.

Coastal Zones

Coastal zones contain valuable ecosystems for both humans and the environment, contributing significantly to the cultural landscape. They have become the preferred choice for settlement of humanity, hosting most of the world's 20 largest mega cities and having enormous infrastructure, and

Figure 2 Progress toward improved drinking water. MDGs, millennium development goals. Source: WHO and UNICEF, 2012. Progress on Sanitation and Drinking-Water – 2010 Update. World Health Organization and UNICEF, Geneva.

generate significant amounts of economic activities (Small and Nicholls, 2003). Africa's coastal environments contribute significantly to the economies of many countries, mainly through fishing, tourism, and as industrial destinations. Coastal and marine resources contribute considerably to the revenue of countries of the region through marine fish catch exports and associated employment although facing increasing threat from development-related activities. Up to 38% of the African coastline of 40 000 km, including 68% of marine-protected areas, is considered to be under a high degree of threat. Uncontrolled urbanization and industrialization including the petrochemical industry are a major cause of coastal degradation. There have been cases where marine pollution has even reached toxic levels from industrial pollution, mining, and oil exploration. Although the level of industrial development on the continent is still relatively low compared to other regions of the world, the rate is accelerating along the coastal zones especially to meet the demand from tourism. Significant growth has been expected to take place in heavily populated coastal regions. In Africa in particular, as poverty drives the population to urban coastal areas resulting in significant increases in the stress on coastal resources, there will be increased risk of flooding, and increased frequency and intensity of storm surge events (IPCC, 2010).

The Fourth Assessment Report (2007) of the IPCC predicts "heavy precipitation events, which are very likely to increase in frequency, will augment flood risk" (IPCC, 2007). These floods will affect life and livelihoods in human settlements in all areas, e.g., coastal zones, river deltas, and mountains. Flooding is also increasing in urban areas, causing severe problems for poor people (Bates et al., 2008; IPCC, 2010):

- Most infrastructure, settlements, and facilities located on or near the shore will be affected by sea level rise, coastal erosion, and other coastal hazards, compromising the socioeconomic well-being of island communities and states.

- Accelerated beach erosion and degradation of diversity of ocean lives will all have impacts on incomes from fishing and tourism.

Climate change will influence the occurrence of extreme events and vulnerability with increased risks such as flooding. Coastal areas would face inundation from sea level rise due to climate variability, wiping off development gains. Inundation of many major cities of Africa from coastal erosion and extreme events and the degradation of marine ecosystems in parts of Africa is expected, with costs of adaptation to annual sea level rise estimated to be in the range 5–10% of GDP (IPCC, 2007).

Mainstreaming Environment, Research, Policy, and Development

Research and Development

Knowledge generation from innovative technology and development research remains a huge challenge to the continent of Africa. For the environment, concerns over ecosystem degradation and climate change have undermined political commitment to the total environment, which is reflected in weaknesses to invest in trans-sector and transdisciplinary research and development. Thus,

- Although trans-sector research is important because it considers interrelationships, networks, and linkages in its goals, it is a costly venture to bridge knowledge gaps and development. There is no doubt that the developed world or richer countries have relatively advanced to extensively engage science and technology in environment and development issues.
- In Africa, the complex origins, problems, and livelihoods of the local population are such that technology and development itself is in turn complicated. As a result, environmental dimensions of such technology and development have been of least concern until the past few years after the hosting of the sustainable development summit in Johannesburg in 2002 which also emphasized the MDGs. The focus of advancing technology with sustainable environmental practice remains at the macroeconomic level for lack of pragmatic research. It is therefore not surprising that several technologies have left in their trails environmental concerns that local and poor people have to continuously deal with.
- A great deal of information and innovation will be required to understand environmental concerns to ensure that socioeconomic development matches environmental sustainability to save Africa's environment.

Policy and Policy-Making Processes

Sub-Saharan African countries are known to be least prepared to respond to extreme events, partly because policies on economic development and poverty eradication hardly consider broader impacts of networks of sectors. Individual sector development policies of many countries especially those related to the MDGs are often silent on potential linkages with our changing environments. Policy frameworks are poorly understood due to data impoverishment and nonexistent environmental indicators. Additionally, the restricted use of data to create scenarios for future planning and linkages with growth and development indicators undermines reliable assessments for policy, hence the need to appraise the following:

- Interventions such as UNEP's Africa Environment Outlook report and the African Ministerial Conference on Environment to help guide planning and macroeconomic policy at country levels to reduce environmental degradation.
- There is need for regional sharing of best practices, experiences, and technologies in Africa in priority sectors to raise awareness, engagement of stakeholders, and for informing decision-making processes at all levels of governance.
- Development frameworks such as the Action Plan of the Environment Initiative of the New Partnership for Africa's Development is about Africa's common and shared sustainable development problems and concern. It provides a framework for establishing strong partnership for the protection of Africa's environment and on the commitments contained in the United Nations Millennium Declaration (UNDP, 2003).
- There still remains a lot of human resource capacity to be harnessed to pursue mainstreaming at the macroeconomy level and this need in itself represents a risk to national and regional policy frameworks.

Conclusion

The environment of Africa is continuously experiencing a changing landscape as a result of increasing human consumption and ecosystem health concerns including environmental change, poverty, and livelihood burden. The challenge of the environment in Africa and its outcomes are heightened by enormous gaps in scientific and institutional capacity to fully understand vulnerability of the human sphere and ecosphere. The numerous environmental degradation outcomes occurring on the continent are potential developmental risks. Nationally, growth and development strategies such as those involving poverty eradication do so at the blind side of other sectors, a mix of their impacts that tend to drive environmental change. There is need for scientifically tested activities that seek to bring the issue of environment and sustainability and more recently inclusive green growth to the doorsteps of the poor in society and policy planners. Thus the understanding of the African environment as a social construct which is inextricably linked to the resource base will constitute the fundamental basis for country level and regional development planning. Africa's cultural landscape therefore constitutes a recipe for the continuous assessment of the evolving state of the environment toward creating future scenarios that provide options for environmentally sustainable development outcomes.

Abstract

This article offers an overview of social worlds, values, and material and nonmaterial cultures of the region south of the Sahara from Mauritania to Cameroon. Attention is paid, in particular, to modes of social solidarity and the cultural dynamics of community formation in West African settings.

This article offers an overview of social worlds, values, and material and nonmaterial cultures of the region south of the Sahara from Mauritania to Cameroon. Attention is paid, in particular, to modes of social solidarity and the cultural dynamics of community formation in West African settings.

The People

West Africa is mainly peopled by Black Africans. Some groups of Berber and Arab descent inhabit the Saharan extremes. A small Lebanese diaspora, distributed mainly along the coast, occupies a role in commerce not unlike the Indian traders of eastern and southern Africa. Malaria deterred European settlement.

Linguistic Diversity

A striking aspect of West Africa is its linguistic diversity (Dalby, 1977). Nigeria, a country of *c.*100–120 million people, covering only about a seventh of the region, is estimated to have between 250 and 400 languages. (The huge expanse of eastern and southern Africa, by contrast, is dominated by closely related Bantu languages.) Language diversity in West Africa mainly reflects *in situ* development of long-settled farming communities, rather than long-distance migration. European languages, especially English and French, became established as public languages during the colonial period.

The Agrarian Base

West Africa divides into three broad environmental and cultural zones – an agro-pastoral desert edge dotted by ancient towns involved in trans-Saharan trade, a coastal rain forest zone shaped by external (sea-borne) commerce (including the Atlantic Slave Trade), and an intermediate zone of drier forest margins and wetter savannas, with a history of endogenous agrarian development dating back several thousand years.

The intermediate zone is the heartland of West African civilization and culture. It is here that local crops, notably white yam (*Dioscorea rotundata*), African rice (*Oryza glaberrima*), and a range of millets ('hungry rice,' pearl millet, and one race of sorghum), were first domesticated. The intermediate zone also provided the oil palm (*Elaeis guineensis*) – the source of oil used in cooking, a mild alcoholic beverage (palm wine), raw material for soap and medication, and ribs, trunks, and leaves from which bags, hammocks, roofs, building frames, and bridges are made.

In the eastern part of West Africa, along the forest–savanna transition and in the river valleys of the savanna, yam–oil palm farming systems prevail. Away from the riverine environments sorghum and pennisetum millet tend to replace yam as staples. The pattern repeats in the western half of West Africa, but with African rice taking the place of white yam (though today African rice is partly replaced by Asian rice, perhaps first introduced by the Portuguese in the era of the slave trade but spread widely only in the last century).

The early rise of a relatively intensive heartland agriculture went hand in hand with other sociotechnical changes, as evidenced by ancient iron working and terracotta art work, suggesting permanent settlement and complex division of labor in the intermediate zone at an early date.

The sacred importance and symbolic significance accorded to intermediate zone crops, even where they have been squeezed out of farming by commercially more productive introductions, is a notable aspect of West African material culture. Wild palms supply a rich red oil that remains an essential ingredient in many rituals, ceremonies, and remedies, greatly favored over the more common plantation substitute. The tasteless white rices of the coastal wetlands are considered no substitute for the nutritionally superior red rices of the interior. From Ghana to eastern Nigeria, yam survives as a preferred staple despite cheaper root crop substitutes. In the *Arrow of God*, Nigerian novelist Chinua Achebe appropriately made the disruption of a new yam festival in eastern Nigeria a striking metaphor for the far-reaching disruption of West African social and cultural values caused by colonial conquest (Achebe, 1964).

Lineage Society: 'Wealth in People'

West African agriculture depends on the hoe. The soils of the wetter savannas and adjacent forests are not suited to plow cultivation. Due to fly-borne disease, pastoralism is well developed only along the desert margins. Elsewhere it is not easy to accumulate wealth in livestock. Successful hoe agriculture depends on abundance of human labor. A central social value in the West African heartland is 'wealth in people.' This has many manifestations. The importance of a chief, for

example, is expressed in terms of wives, children, and domestic dependents, rather than through holdings of land and livestock.

But in hoe agriculture, timing and coordination of labor are as important as numbers of workers, especially in strongly seasonal savanna cultivation systems. Interhousehold labor cooperation, and the social values, crop types, and farming practices conducive to such cooperation figure strongly in West African agrarian social systems. In the old days, the young people of an entire community might pool their labor for farm operations. Today it is more likely that they will form cooperative gangs to tackle backbreaking and time-constrained jobs on a rotational basis. Where agriculture is commercialized labor gangs ply for hire.

Labor cooperation is a practical manifestation of egalitarianism among the young typical of West African heartland social organization. This egalitarianism is frequently fostered through initiation into so-called 'secret' societies, widespread and still powerful in parts of the region. Such societies typically tend to support social values among the young, strikingly in contrast with hierarchical values prevailing in the world of the elders. From Guinea to Cameroon, the senior grades within secret societies form a ladder along which elders compete to advance.

French Marxist anthropologists in the 1960s and 1970s wrote about this typical opposition between youthful egalitarians and ranked elders, as 'lineage' society, or a 'lineage mode of production,' clearly differentiated from feudal relations found in medieval Europe and elsewhere (Seddon, 1978). It was conceived that elderly elites, drawing on the language of kinship and descent for legitimating, reproduced themselves at the expense of the labor of cadets. According to some authors this amounted to a kind of class conflict. The explanation was controversial. An alternative explanation is that typical agrarian societies in the West African heartland are the complex outcome of a number of competing principles of social solidarity, none of which, by itself, can sustain a satisfactory community life over the longer term.

Agrarian Social Solidarity

As suggested, two principles of social solidarity often encountered in West African heartland social formations are egalitarianism and hierarchy. They offer quite distinct approaches to the problems of keeping social groups together (Douglas, 1993). Neither, alone, can sustain a community except in the short term. Compromise is an essential prerequisite for survival.

In a land-abundant setting, hierarchs may be able to do little to prevent youthful egalitarians from forging their own breakaway communities. But breakaway youthful egalitarians quickly run into problems of leadership. Youth labor gangs often have their own 'government,' and spend large amounts of time in dispute settlement, to the detriment of the work in hand. Charismatic leadership sometimes helps the egalitarians to go-it-alone for a time, but as with sectarians everywhere, splits lie around the corner. The more settled authority of the elders offers clear advantages. The typical West African agrarian compromise seems to have allowed for the emergence of spheres of partial autonomy for women and youth within a more complex social totality presided over by elders (and ancestors). Achieving such coordination and compromise without recourse to strong centralized political institutions was often the work of the 'secret societies' (for both men and women) found particularly in the Upper Guinean section of the Atlantic Coast in the western half of West Africa, and more widely in the region. In communities welded by initiation and secrecy, a social contract renewed or reinforced typically manifests itself from time to time in dramaturgical terms (often as masquerade display). The arts of masking are among the greatest manifestations of West African material culture and societal values.

The test of any mode of social solidarity is the extent to which it permits humans to flourish. A central fact about many decentralized ('stateless') societies of the West African heartland is that they often sustained denser populations than adjacent territories with a history of strong (and often strongly oppressive) central institutions (Middleton and Tait, 1959).

Society and Culture at the Margins: Coast and Desert Edge

International trade rather than agriculture was a mainstay of life at the coast and on the desert edge. It is in these regions that we first see most clearly the emergence of a trade-related West African urbanism, with its own distinctive institutions and cultural values. Along the desert edge, long-distance trade was associated with the early spread of Islam, and with Islam came literacy, science, and an enhancement of bureaucratic capacity. A process of modernization and reform took shape among desert-edge trade-related towns and polities in the late eighteenth century, and by the mid-nineteenth century larger regional formations, such as the Sokoto Caliphate (Last, 1967), covered a large part of what is today northern Nigeria. Two interior languages – Hausa and Maninka (Dioula) – developed some importance as media of regional communication, along with written Arabic for letter writing and record keeping.

At the coast, trade was stimulated by European contacts from the fifteenth century. Christianity gained several footholds, and small ports and polities oriented to the Atlantic trade developed, at times ruled by mercantile elites of Afro-European descent. Coastal trade pidgins, drawing first on Portuguese and later on English, developed into a distinctive family of mutually comprehensible English-oriented pidgins and creoles, today perhaps as widely spoken in coastal urban centers from The Gambia to Cameroon as Hausa or Dioula, the trade languages of the savanna, are spoken in interior West Africa. The English-oriented pidgins and creoles have considerable importance in coastal West Africa as means of communication among the nonelite, and in popular music and entertainment (Todd, 1984).

Globalization is no new phenomenon in desert-edge or coastal West African communities. From an early date children of trading elites might be sent to Cairo or Liverpool for their schooling. Nelson's victory against Napoleon's fleet at the Battle of the Nile in 1803 was known in Kumasi within weeks; that the news made sense at all implies a sophisticated world map in the West African interior. The typewriter was in

use among Christian converts in the interior of Yoruba-speaking country (now western Nigeria) within decades of its invention. The colonial telegraphs, and now the modern satellite phone, are among the communication means through which globally dispersed West African families have maintained and developed their wide networks of social contacts in the modern period.

Conversion to the 'world religions,' Islam and Christianity, tells us about growing global awareness even at early dates. Coastal linguistic creolization was part of a larger process of cultural creolization that helps explain the international outlook and mobility of many West Africans today (Hannerz, 1987). Diaspora communities of West Africans, often involved in trade, are found in most world cities today, and not just in the capitals of the former colonial powers. It is not uncommon to find street children or unemployed youth in Dakar, Douala, Freetown, or Lagos with a better grasp of politics and world issues than well-educated teenagers in Britain, America, or France.

The Impact of External Trade on Social Values

Arguments and compromises over social values took different forms under the impact of long-distance trade from those already described for heartland agrarianism. We need to distinguish internal and legitimate trade from the slave trade. Vigorous internal trade, exchanging forest and savanna products (notably cattle, kola nuts, and salt) was a stimulus to social and cultural innovation in a number of communities located on major north–south internal trade routes.

Typical adaptations to long-distance trading (Cohen, 1969) included the development of culturally distinct diasporas (Hausa cattle dealers in western Nigeria, or Fula kola dealers in Sierra Leone for example). At times agrarian elites maintained some control of diaspora trading groups through intermarriage. At other times diaspora communities have been confined to special settlements (Zongo, Sabon Gari) at the edge of villages or towns.

In other cases, women or youth have been free to exploit the potential of semiautonomous social spheres to build up commercial activities. Igbo young men from eastern Nigeria have long adapted the ganglike structures of the labor company to itinerant trading (in, for example, second-hand clothing, cloth, or motor spares). Agrarian labor cooperatives often double, or develop, as rotational savings and credit associations for the purposes of commerce.

Women traders are prominent throughout the West African costal and forest zone, but especially so in Ghana and southern Nigeria. Large-scale female traders, sometimes with little or no formal education, are to be encountered traveling the world, often in groups, perhaps as likely collecting car spares in Taiwan, as exporting a consignment of red palm oil to London. West African women's involvement in commerce typically began with local and regional foodstuffs trade neglected by the colonial commercial houses. The extensive yam trade from the Middle Belt interior to burgeoning colonial coastal cities of Ghana and Nigeria would be an example. In patrilineal communities, women are life-long brokers between kin groups. Taken in conjunction with the gender solidarity fostered by initiation, this helps set up an extrahousehold social space in which women's commerce has tended to flourish.

But we need to be careful not to impute modern ideas about individualism and enterprise to the development of West African trading relationships with the wider world. Frequently overseas or trans-desert trade was the monopoly of rulers who kept a tight rein on contacts and commercial information. Those controlling the trade-based polities of coast and desert edge were more likely to be monopolists and autocrats than agents of an enterprise culture. In the nineteenth century, the spread of firearms allowed trade-oriented rulers extensive use of socially unaccountable force. A not dissimilar militaristic adventurism has reasserted itself in some parts of West Africa (notably in Liberia and Sierra Leone) as the twentieth century ends, prompted by an international political vacuum and a surfeit of cheap weapons from the ending of the Cold War.

The mode of social solidarity that tends to predominate under war-lord autocracy is not individualism but fatalism, a fact illustrated in the 1997 elections in Liberia, where a war-weary population voted for the strongest of the faction leaders from a destructive seven-year civil war, reasoning the most powerful autocrat was the best guarantee of a kind of peace. Fatalism is little appreciated as a basis for social solidarity, but may be preferable to the mayhem of a bush civil war. Here we have an insight into why social life on the West African frontier so often seems to have been characterized by quietism, and a subsistence-oriented conservatism, rather than by the expansive individualism associated with the making of the American frontier (Kopytoff, 1987). The attitude is 'we make no demands other than to be left to get on with our lives.' The old heartland agrarian social mix continues to have a certain basic appeal where the alternative is the postmodern violence of late twentieth century conflict in Liberia and Sierra Leone.

Social Consequences of the Slave Trade and Colonial Rule

Perhaps between 10 and 15 million West Africans were sold into Atlantic slavery from the sixteenth to nineteenth centuries, and 8–10 million into trans-Saharan slavery. In addition to the adverse demographic impact, in a region dependent on labor-intensive hoe agriculture, the conversion of human beings into commodities dealt an enormous blow to the trust essential to the functioning of many social institutions (Inikori, 1982). It is hard to overestimate the continuing consequences of the slave trade for the evolution of social values in West Africa. Fatalism, fear of entrepreneurial individualism, distrust of chiefs, and undue respect for autocrats in return for basic security are among the symptoms of the damage. Distrusts inherited from the era of the slave trade remain a factor in the nihilism of much of the current youth-led violence blighting the region. How ordinary West Africans continue to come to terms with the harsh social legacy of the slave trade is also very apparent in popular religion, in ideas about chiefs as shape-shifting witches, or through divination and possession as ways of addressing old betrayals and coming to terms with disastrous breakdowns in family or community solidarity (Shaw, 1997).

Colonial protection in West Africa arose from initiatives to eliminate the slave trade, beginning with the assumption in 1807, by the British Crown, of administrative responsibility for Sierra Leone, an eighteenth century West Coast settlement for freed slaves founded by British Christian philanthropists. Ending the slave trade became the pretext for a series of moves by industrializing European powers to control resource extraction and guarantee markets for their own manufacturers. By the end of the nineteenth century, West Africa had been carved up by the Germans, French, and British (Crowder, 1968).

Colonial rule at the beginning of the twentieth century was militaristic, often formally racist, and based on a protectionist principle of imperial preference. Although colonial regimes built railways and some roads, and Christian missions under colonial protection introduced school education and Western medicine, colonial autocracy did nothing to repair the adverse social legacy of the slave trade.

Postcolonial Social Trends

Many leaders in postcolonial West Africa adapted colonial autocracy to their own ends, paying more attention to external stimuli – notably Cold War incentives – and less to local accountability. A spate of coups replaced civilian with military autocrats. Economic development was hindered by unwise investments in prestige projects and by corruption. Former colonial powers embarked on political intrigue to control rich natural resources, for example the role of France in the Nigerian civil war (1967–70). The bright hopes of independence dimmed, and the region lost many of its talented professionals through international migration. Inflows of development aid and migrant remittances became essential parts of most West African economies.

From the 1980s the international financial institutions, and Western aid donors, attached conditions to aid grants in the hope of fostering a transition to a market economy, but without taking full account of the way in which adverse social and institutional developments under the slave trade and colonialism had prevented the development in West Africa of the internal checks and balances between state, market and civil society on which a modern market-based society depends.

Some West African rural groups retained access to herds or large expanses of land for shifting cultivation, and could retreat toward heartland subsistence, but others increasingly found that the system of circulatory migration, in which young people migrated to the cities in search of laboring work, in order to save money for a successful return to village life as a respected elder, had begun to fail. Increasingly, young migrants might find that land had been leased to tenant farmers in their absence, or acquired for commercial development by agribusiness. Unable to reintegrate within rural society, young migrants began to question traditional social values and cultural norms. Some became adherents of populist leaders proposing radical change.

The 1990s was a decade of civil war, in which rural insurgency was fed by a youth population bulge. By now, over half of all West Africans was below the age of 18. These insurgencies severely damaged isolated rural communities in the Upper West African forest belt, the Niger Delta and the desert edge, but were unable to make good their promise of profound and sustained change for young people. However, armed conflict was often prolonged by the involvement of international venture capitalists and private military companies, seeking access to lucrative timber and mineral resources, and able to supply cheap arms and military know-how rendered redundant by the ending of the Cold War.

The storm blew itself out in the first decade of the twenty-first century, as peacemakers switched their attention from negotiating with populist mobilizers of youth to sanctioning the diamond dealers and gun runners, and to addressing more basic underlying social issue, notably youth unemployment. Promises of skills training and jobs attracted some of the young fighters out of the bush. Others continued, under the perhaps more durable appeal of political Islam. The Islamist group Boko Haram bolsters its insurgency in northern Nigeria with a rejection of school education, and the world of 'modern' work to which such education promises to lead. Much remains to be done to stabilize a younger generation denied educational opportunities and jobs by earlier economic malaise.

Most recently, the social landscape in West Africa has begun to experience a further transformation under the impact of China's expansion into the region in search of raw materials for its global industrial machine. Being interested in bulk mineral extraction (iron ore, bauxite, mineral oil), China cannot interact with West Africa in the manner of the hit-and-run opportunists of the conflict years in the 1990s. Chinese investment is focused not only on mineral concessions, but also on the infrastructure of transport, power, water, and telecommunications necessary for long-term extraction ventures.

Other investors have been attracted by this Chinese-led upturn in the region's economic fortunes. Some large-scale overseas ventures have attempted to learn from the lessons of the near collapse of large parts of West African society in the 1990s. Land deals – e.g., for biofuel and energy developments – attempt to incorporate a variety of rural stakeholders, in addition to generating welcome employment opportunities for youth.

At the same time, governments have become more democratic, open and accountable. State revenues (boosted by the rapid improvement in economic fortunes) are now better able to provide for social needs such as basic education and health. But there remain major concerns over the sustainability of the current rapid levels of development.

Signs of environmental fragility abound. Rapid urban development is chaotic and uncontrolled, leading to potentially destabilizing future problems of pollution, congestion and epidemic disease. Most of the new employment in extractive industry and infrastructure development is unskilled and low paid; skills training remains a major bottleneck. The undermining of traditional land rights threatens also to dismantle an important safety net for the poorest groups. Material inequality is manifest. Disgruntled youth still have their rallying points – not least militant Islam.

Afrocentric Approaches to Social Work

Abstract

This article explores the use of 'Afrocentricity' as a conceptual framework for social work practice and service intervention in African-based communities. As developed and defined by Asante (1980), Afrocentricity is a theory of social change that affirms the importance of African history, culture, and values as a foundation for understanding the contemporary experiences of African descendant peoples throughout the world. This article will examine the emergence of the concept and advocates efforts to link Afrocentricity to social work practice in the African diaspora.

Afrocentricity and Social Work: Early Beginnings

In the field of social work, Africentric, Afrocentric, and African-centered are concepts, often used interchangeably, to describe the efforts of theoreticians and practitioners to integrate and fully utilize an innovative approach to social work intervention, which places the African experience at the center or as the central focus of practice. The growth and expansion of this initiative can be traced directly back to the early beginnings of the Black Social Work Movement (BSWM) in America. The BSWM harnessed the energies of a radically progressive group of Black social work professionals who desired to alter traditional social work practice to fit the needs of the people they served. These visionary Black social workers were committed to the purpose, goals, and mission of the social work profession and embraced it as a viable social change strategy to aid the Black community. From its earliest inception, social work, which can best be described as a profession committed to the enhancement of the quality of life for individuals, families, groups and communities, expressed a particular interest in serving the needs of the poor, socially disadvantaged, and vulnerable populations (NASW, 1977). Social work proved to be a popular choice for many college-educated, career-oriented Black professionals.

The Black Freedom Movement

During the height of the Civil Rights and Black Power movements that rocked the United States of America in the mid-1960s, Black social workers began to question their role in the struggle for Black freedom and liberation. The social turmoil that erupted during this era forced many Black professionals to reexamine their relationships with the Black community. Located at the nexus of social policy implementation and service delivery to the masses of poor Black people, many professionally trained Black social workers questioned the relevance of their knowledge and skills as it related to the uplift and improvement of the quality of life for their clientele. Frustrated with their roles as ineffective 'state guardians of the poor,' Black social workers sought to connect with other disaffected workers to discuss a more radical approach to practice. As the network of social activists expanded throughout the community and, eventually, throughout the nation, the BSWM was born (Reid-Merritt, 2010).

The BSWM emerged as a grassroots movement of highly trained social welfare workers and community activists seeking effective social service intervention with positive outcomes. It was one of numerous organized efforts that contributed to the larger, mid-twentieth century movement for Black freedom (Karenga, 2010). As interest grew, the activists formally organized, and in May 1968, founded the National Association of Black Social Workers, Inc. (NABSW). This organization would lead the national and international efforts to transform social work and the delivery of social work services in Black communities (Reid-Merritt, 2010). For example, in California, Georgia, Illinois, Michigan, New York, New Jersey, Pennsylvania and Tennessee, local chapters affiliated with NABSW challenge child welfare agencies on practices regarding the removal, placement, and adoption of Black children; a national strategy is developed to resist state efforts to regulate the practice of social work through licensing; and social work graduate schools face demands for changes in faculty staff, student population, and curriculum that are reflective of the racial diversity that exists within the surrounding community.

Seeking New Knowledge

The conscious use of race and culture as major factors to be considered in social work intervention in the Black community was initially described by NABSW and other socially progressive practitioners as 'Black social work practice.' LaVerne McCummings (NABSW, 1970), a BSWM early participant, social activist and NABSW leader, described the initiative as a new form of social work practice 'based on liberation rather than adjustment,' Numerous scholarly efforts were made to help articulate this new form of practice. Better (1972) was among the first to argue the benefits of racially conscious Black social work practitioners. She noted that an awareness of their role as Black professionals, employed as agents of social change within their own communities, would enhance their effectiveness and the delivery of social services. Mathis (1972) promoted the concept of 'nation-building,' where the role of race and identity was clearly understood as a primary responsibility of the Black social work activist. The goal of nation-building was the liberation of the Black masses from "the shackles of physical, emotional, economic, and political dependency" (Mathis, 1972: 2). The racially conscious Black social work practitioner could achieve these goals by rooting themselves in an understanding of the extended Black family;

committing themselves to the development of independent Black institutions; freeing themselves from white social work values and concepts; and operating from a value system based on African communalism. Gilbert (1974) concurred, calling for 'a fundamental change' in the primary goal of the social work intervention in the Black community to make it more liberating than oppressive. All acknowledged the need for a new form of 'cultural grounding' for Black social workers, reflective of their identity and heritage as Black people.

Black scholars and practitioners struggled to identify the new knowledge, concepts, and theories needed to enhance the effectiveness of social work practice within Black communities. And, during the first full decade of the BSWM, various theories, philosophies, and value systems were used to buttress the movement toward a more African-centered approach, including, but not limited to, Kawaida and Nguzo Saba (Karenga, 2010), strengths (Hill, 1972) and nigrescence (Cross, 1971, 1980).

Karenga's (2010) Kawaida theory spoke to the need for a cultural revolution for Africans in America, emphasizing the need for Black people to embrace their own African heritage. He (2010) develops a set of seven principles, described as the Nguzo Saba, which guides the transformative process. Identified first in Swahili and translated into English, they include *Umoja* (Unity), *Kujichagulia* (Self-Determination), *Ujima* (Collective Work and Responsibility), *Ujamaa* (Cooperative Economics), *Nia* (Purpose), *Kuumba* (Creativity), and *Imani* (Faith). Hill identified five common strengths that were prevalent in Black families. These included a solid work ethic, high aspirations for their children, broad kinship bonds and support networks, role flexibility between the men and the women, and a strong religious foundation. Cross (1971) spoke in *The Negro to Black Conversion Experience*, which enabled a young, racialized generation of Black to understand their internal, emotional struggles surrounding their identity. Nigrescence, or the process of becoming Black and being able to accept one's Black identity, occurred in five stages: pre-encounter, encounter, immersion, emersion, and internalization. In each stage the individual is confronted with conflicting social images about his/her Black identity until transitioned to the final stage of internalization where one finds a level of comfort.

However, it was Asante's (1980) introduction of the concept of Afrocentricity that changed the language of blackness and allowed the progressive Black social work practitioner to more accurately describe this new approach to practice.

The Afrocentric Approach

In *Righteous Self-Determination: The Black Social Work Movement in America*, Reid-Merritt (2010: 132) posits that Asante's theory of Afrocentricity "entered scholarly discourse at a time when many scholars struggled to reformulate and re-conceptualize their basic orientation to the study of African people." More than any other emerging concept in the scholarly literature, this intellectual contribution aided Black social workers in their search for the development of a culturally grounded and racially specific approach to social work practice. She (Reid-Merritt, 2010: 134) notes further that Asante's theory "provided the language and cultural grounding needed to guide Black social workers toward the development of nontraditional, alternative approaches to understanding the Black community from an African-centered perspective."

In his ground-breaking work, *Afrocentricity: A Theory of Social Change* (1980), Asante provides a foundation for understanding the contemporary African world experience. He argues that African descendant peoples who have lived under the forced cultural, social, political, and economic hegemony of European dominance throughout the world, experience disorientation and dislocation in contemporary societies. The history of invasion of the African continent, the transfer of millions of Africans to the Americas, the Holocaust of Enslavement, the colonization of Africa, and the ongoing European domination that followed resulted in a 'de-centering' of the African mind, body, and soul. A positive, reaffirming form of social and cultural identity had been lost. The process of reclamation required re-centering oneself in the history, values, and culture of an authentic African past. This social and personal repositioning would help to nurture the development of a more viable and life-affirming 'Afrocentric reality' (Asante, 1980, 1990; Reid-Merritt, 2008).

As the contours of the paradigm continued to unfold, Black social workers began to embrace the concept of Afrocentricity as a new framework for practice. Discourse on black social work practice was transformed with the use of the words Afrocentric, Africentric, and African-centered. Nowhere was this more evident than within the BSWM and the national and international gatherings sponsored by NABSW (1970–2010). For example, NABSW traveled, with large groups of black professionals, to the Caribbean, South America, and Africa, hosting international conferences and spreading the word about the commonalities of the African descendant experience throughout the world. And the national conferences were visited by Black social workers from the international community, including the Bahamas, Brazil, England, Germany, Jamaica, and Nova Scotia. There were common themes: racism, oppression, powerlessness, and despair, all met with a spirit of unity and willingness to fight for the uplift of the community. Both in professional practice and social work literature, Black social workers began to discuss the need for an African-centered approach as numerous scholars began to articulate ways in which Afrocentricity could be applied to various forms of social work practice (Harvey, 1997; King, 1994; Swigorski, 1996; Schiele, 1997, 1996; Graham, 1999). But how was this best achieved and integrated within the discipline?

Afrocentric Social Work: Theory and Practice

As a discipline and practice profession, social work requires a knowledge, value, and skill base to help guide its practitioners toward effective social service and human interventions. Its knowledge base, in particular, borrows heavily from other disciplines, including history, psychology, sociology, anthropology, political science, economics, and other social and behavioral sciences, to form a foundation for understanding the human condition. However, recognizing that traditional sociohistorical literature was Eurocentrically oriented and

noninclusive of the experiences of African people, Black social workers sought to build a new intellectual foundation. The existing knowledge base was inadequate; new theories, values, and skills, reflective of an African-centered worldview, were required. Thus, Black social workers began to focus their discourse around the need to replace the traditional social work knowledge base with Afrocentric knowledge. And they were not alone in their pursuit; Black scholars in other traditional disciplines were experiencing a social and intellectual transformation as well.

In the US, for example, in psychology, the widely popular and traditional theories of Freud, Erickson, Jung, and Adler (Beckett, 2002; Miller, 2009) were being replaced by Akbar (1981), Nobles (1986), Kambon (1992), and Myers (1988). These emerging black intellectuals and practitioners worked on developing innovative theoretical approaches to transform discussions of the practice of black psychology into Afrocentric approaches. In sociological theory, discussions on the impoverished, socially maladjusted, culturally deprived black family (Karpas, 1964; Lewis, 1966; Moynihan, 1965) were replaced with a strengths, vitality, and survival orientation that highlighted the adaptive qualities and capabilities of African American families (Hill, 1972; Sudarkasa, 1980, 1981; McAdoo, 1981). These scholars argued the merits of the aforementioned characteristics as enduring qualities that contributed to the flourishing of the culture and the people.

The discourse in social work emphasized the need to incorporate an Afrocentric approach into all areas and fields of practice, including child and family services, educational programs, mental health services, drug abuse/addiction prevention and treatment programs, pretrial/incarceration/re-entry programs, community development, and social policy. And new programs, utilizing the Afrocentric perspective, did emerge. These included rites of passage programs for youth; parenting programs; community-wide educational programs in African and African American history, art, and culture; community-based Kwanzaa celebrations; and the reintroduction of African rituals into traditional African American cultural and social events (Monges, 1990; Harvey and Rauch, 1997; Reid-Merritt, 2010). Practice approaches may have differed in their particular methods and techniques, however, the basic philosophical grounding remained the same: The African past was a central component of the modern-day black experience; African descendant people were a self-determining population with the right to obtain 'cultural agency'; social work interventions must be based on the realities of the African world; and practitioners must start with a fundamental understanding of the history, values, ideals, culture, and heritage of African people.

Black social workers who espoused a belief in the Afrocentric approach may have appeared to some to be the new renegades in the profession, however, recognizing and accepting the unique qualities of human populations was consistent with the core values and principles of social work. And, Black social workers were determined to use all aspects of their professional education and training to better serve their own communities, which were too often negatively described as problematic havens for 'minority' group members.

Decades after the release of Asante's (1980) pivotal work, efforts to reconceptualize social work from an Afrocentric perspective continued to unfold as practitioners and scholars challenged the dominance of the European worldview. The new, emerging literature was replete with the words Afrocentric and Afrocentricity. And while these were the most popular terms used (Schiele, 1990; King, 1994; Mathis, 1994; Daniels, 2001; Graham, 1999; Reid-Merritt, 2010), others (Roberts et al., 2000; Harvey and Rauch, 1997; Clegg, 1997; Crawley, 2001; Harvey and Hill, 2004; Bent-Goodley, 2005) preferred to use 'Africentric' or 'African-centered' in their challenge to Eurocentric approaches. Each of their contributions supported the expansion of the developing paradigm for Afrocentric social work practice.

The examples are plentiful. For Schiele (1996: 285), the Afrocentric approach offered the opportunity to apply 'traditional African philosophical concepts as a foundation for a new social work practice model.' For Graham (1999, 2005: 71), a leading Afrocentric scholar from the UK who now resides in the US, the new Afrocentric approach to social work incorporated the history, values, and beliefs of an African-based culture and embraced "an African-centered worldview as the basis for theories and models of practice." Mathis (1994: 4) added that an African-centered approach required a new set of values as the basis for social work practice in Black communities. Borrowing from Maatian philosophy, which was based on traditional Egyptian religion, thoughts, practices and beliefs, the seven cardinal values of truth, justice, propriety, balance, harmony, reciprocity, and order replaced western values based on individualism, competition, independence/dependence, and materialism.

For micro-level practice intervention, Crawley (2001: 127) utilized the Afrocentric perspective to provide "a framework that allows clients to connect to a vital sphere of their identity – that is, being of African descent." And Harvey and Rauch (1997: 164–8) described a psychosocial, Afrocentric model that utilizes RIPSO or Principles of Afrocentricism. These value principles are identified as: "responsibility, reciprocity, respect, restraint, reason, reconciliation, interconnectedness, interdependence, inclusivity, participation, patience, perseverance, sharing, sacrifice, spirituality, cooperation, discipline and unconditional love." While many scholars and practitioners continued to incorporate an Afrocentric perspective, fully articulated Afrocentric practice models are still in the early stages of development. An African-Centered Approach to Social Work (AFCENA) is an example of one of these emerging models.

AFCENA: An African-Centered Approach to Social Work Practice – A Model for Practice

AFCENA was introduced to the Black social work community by Reid-Merritt (2010) at a national Policy institute sponsored by NABSW in 1995. AFCENA "fused African-centered contemporary intellectual thought with the fundamental principles, goals and purposes of social work and recognized the significant contributions that good social work practice could have on the African American community" (Reid-Merritt, 2010: 193). This model provided a broad, conceptual framework which specified the building blocks needed for Afrocentric social work practice and offered a comprehensive approach, applicable to the Black community as a whole, rather than its fragmented parts. It is applicable to every area

of practice, including clinical intervention, community organization, policy development, education, and research.

The context of the model is bound by a communal framework, i.e., the depth of knowledge, understanding, and appreciation for the socially unique characteristics of African descendant communities, which speaks to the *collective inheritance* of the people. As a prerequisite to any form of practice intervention in the Black community, social workers must be knowledgeable about the historic cultural ties that bind the community together. This collective inheritance focuses on an accurate historical account of past challenges and achievements and includes (1) an acknowledgment of the importance of *ancestral wisdom*, which has been passed down from generation to generation; (2) an acceptance of the pervasiveness of *epic memory*, which provides a deep remembrance of the behaviors, habits and customs of the people; (3) the ability to embrace the community's *cultural legacy*, which provides an active, continuous reflection on how people choose to live their lives; and (4) a belief in the future guided by *victorious visions*, which help to galvanize the community's efforts to strive toward greatness. This historical cultural knowledge base would prove valuable for all professionals, but deemed essential for the Afrocentric social work practitioner. However, a simple question must be raised: How does one gain proficiency in this area? There are limited expectations that this specialized form of knowledge would be found within traditional schools of social work; rather, the Afrocentric social worker must seek out and design a course of study that provides the in-depth knowledge needed for specialized practice in African-descendent communities.

There are five basic components to the AFCENA model, including an Afrocentric perspective, knowledge/experience, values/ethics, skills/behaviors, and spirit/life force. The components of this circular model remain fluid and accessible throughout all stages of the helping process. "They are constant, flowing and interchangeable. The beginning is the end and the end is the beginning of the process" (Reid-Merritt, 2010: 194). Afrocentricity or the Afrocentric perspective provides a common framework for understanding and analyzing the history, philosophies, religious beliefs, and cultural practices of African people. The knowledge base is buttressed by the infusion of theoretical perspectives grounded in the African worldview. This is critically important in the areas of human growth and development, socialization and community development which focus on understanding the human condition. Experience or 'practice wisdom' helps the practitioner verify the relevance and applicability of new theoretical approaches as they are tested in the helping process.

The principles of Nguzo Saba and Maat serve as the value base for Afrocentric practice, and the NABSW Code of Ethics serve as a constant reminder that "I regard as my primary obligation the welfare of the Black individual, Black family and the Black community and will engage in action for improving social conditions. I give precedence to this mission over my own personal interests" (NABSW, 1970). Helping skills, including engagement, observation, listening, questioning, verbal and nonverbal communication, must be those which are valued, appreciated, and understood in African-based communities, and include communication patterns attuned to the call and response and the participatory nature of the culture. And professional behavior is a reflection of one's ongoing commitment to the uplift and empowerment of the people and community, not one's primary commitment to bureaucratic agencies or ineffective government policies. Finally, we are all in possession of a spiritual life force, the very essence of our existence, which provides meaning to life, motivates us to live our life to the fullest, and helps us interpret our relationship with the universe. The Afrocentric social work practitioner remains fully cognizant of the need to help those who have been temporarily dispirited by personal obstacles and/or social oppression to resecure their place on life's continuum.

The conceptual practice models also provide descriptive details on the interactive system, e.g., the place of contact between the social worker and the client system. This is where the work is done, where problems are manifested, or where success is achieved. There are multiple practice settings in the field of social work. And while a small percentage of the profession has chosen to engage in individual private practice, most social work intervention is sponsored by government and private agencies and foundations. AFCENA describes the point of contact between the social worker and clientele/community as the interactive system. The Afrocentric social worker cannot operate in a vacuum. They must be mindful of the major external factors which impact the client system and the delivery of social services to Black communities. These factors include race, gender, class, religion, geographic location, and political ideology. Moreover, the worker must remain cognizant of the mission, purpose, and goals of social work intervention. Resistance to service, which may appear to be more prevalent in oppressed communities, must be countered with optimism and hope for positive change. Social work service intervention outcomes must go beyond the mere return of individuals, families, and communities to survival status; rather, service intervention should lead to personal and social transformations that help individuals, families, and communities share in the abundant resources of society and thrive under new social conditions and arrangements beneficial to all.

Proof

"Afrocentric approaches to social work offer the greatest potential for the development of racially and culturally-specific models of social work practice intervention in the Black community" (Reid-Merritt, 2010: 196). However, the theories, models, and perspectives utilized to support Afrocentric social work practice have and will continue to be challenged by mainstream social work. The profession's movement toward *evidence-based practice* reminds us of the need to provide proof of the effectiveness of these new approaches to practice. Documentation of our success, and failures, must be supported with rigorous investigations, ongoing research, and the publication of our results in the social work literature. This would prove valuable not just to the advocates of an Afrocentric practice, but to all those who seek alternative approaches to social work practice with marginalized, oppressed, and socially disadvantaged communities.

Age and Crime

Abstract

Current knowledge about age with regard to crime has a solid foundation amassed with promising theory and research. There is certainty among social scientists about the existence of a relationship between crime and age; that the aggregate age of criminals peaks at late adolescence and early adulthood; and that this 'age-crime curve' exists in both aggregate and individual level data. Scholar perspectives vary on the nature of individual behavior within the curve, patterns, and determinants of criminal activity early in life; the trajectories represented by the aggregate curve; and desistance of criminal activity in middle age or late life.

The life course is often described as a 'pathway,' implying a linear process where a person's life, viewed as a whole, has a direction based on observed behavior and expectations for future behavior. One's life may be said to change direction, 'taking a turn' for the worse or better, based on behavioral changes. The life course has also been described as a series of relatively discrete phases in human development: childhood, adolescence, transitional adulthood, middle adulthood, and the early and late older years. Each stage is associated with distinctive behavioral roles, expectations, and social resources. Related to the concept of stages are the transitions between stages and the timing of such transitions.

These different conceptions of the life course are generally compatible, as both allow social scientists to examine behavior as part of a larger whole of human experience. With regard to the study of crime and deviance, some controversies do arise when considering how much significance the life course has in explaining behavior.

As social roles and expectations change with age, deviant behavior and delinquency have been tied to the life course. The longitudinal study of crime has developed from empirical observation of criminal behavior by age and observations in support or in contrast to the normative expectation that those who participate in deviance, particularly crime, age out of such behavior. The developmental and life course subfield in criminology gained momentum as a result of a series of debates on the importance of taking age into account in theory and research on crime, on the stability of deviance through the life course, and on the types and number of trajectories in a population. These debates are fundamental to the concept of the criminal career, a notion which has itself been debated publicly for a century (Glueck and Glueck, 1940; Lemert, 1951; Erikson, K.T., 1962, 1966).

Dimensions in DLC Criminology

Toward understanding the relationship between age and deviant or criminal behavior, published longitudinal research has examined age of onset, i.e., when the behavior under observation began, usually described in the binary as early or late onset. Prevalence, an aggregate measure of whether or not individuals participate in certain deviant acts, is examined separately from frequency – the incidence of deviant behavior among those individuals who do participate (Blumstein et al., 1985; Petras et al., 2010). Both variables contribute to the relationship between age and crime, and both are influenced by variables demonstrated to affect criminal behavior. Severity, a measure of the extent self or societal harm, can also vary by age.

Other longitudinal dimensions include career length or persistence, also expressed as continuity (e.g., Nagin and Farrington, 1992a; Ezell and Cohen, 2005; Bushway et al., 2009). Desistance, the cessation of the behavior under observation, is of interest to criminologists and other behavioral health scientists such as those studying addiction (Bushway et al., 2009; Petras et al., 2010; Blonigen, 2010; Hser and Anglin, 2011), as is intermittency, gaps in the behavior of interest, which has been shown to increase with age (Baker et al., 2013).

The concepts mentioned so far are generally homotypic patterns, i.e., the continuity or change of one type of behavior. Heterotypic longitudinal patterns, i.e., qualitative shifts in behavior, are also of interest (Laub and Sampson, 2003; Farrington et al., 2006). Nieuwbeerta et al. (2010) found 'an age–diversity curve,' in which there was evidence of diversification in delinquent behavior between early adolescence and young adulthood and then specialization later in adulthood. Additionally, the specialization is observed even as there is a general decline in frequency with age.

The notion of turning points, life events, or transitions that marks major changes in behavior or status is also an important item on the life course research agenda (Laub and Sampson, 2003; Teruya and Hser, 2010). Good marriages and parenthood are associated with decrease or desistance of delinquent behavior (e.g., Laub et al., 1998). Motherhood, to an even greater extent than marriage, is associated with decreased delinquency in disadvantaged communities (Kreager et al., 2010). The notion of turning points also applies to onset, including late onset, of criminal or deviant behavior (Carr and Hanks, 2012).

The notions of age-related cognitive shifts and identity transformation have proven to be key concepts in elucidating the process of desistance (Veysey et al., 2013; Bushway and Paternoster, 2013). Although measurement problems still preclude large-scale quantitative investigation of these internal and personal dynamics, such processes are considered 'most promising' theoretical explanations of desistance, including disengagement from gang affiliation (Pyrooz and Decker,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.45043-9

2011; Sweeten et al., 2013; Flores, 2013). Cognitive transformation has been found associated with treatment and policy interventions; and these transformations have been noted as affecting a variety of criminal careers, including sexual offending (Harris, 2014). Thus, consideration of the effect of age on crime also requires consideration of policy-relevant issues, such as intervention, treatment, and selective incapacitation (Hser and Anglin, 2011; Blumstein et al., 1988).

These time- and age-related factors in a person's behavior link deviant behavior to the general knowledge base about human development. Age or developmental stage is thus considered an important variable, often found to be a risk or protective factor in behavior. However, there was not always consensus on the importance of age and the life course.

Age, Crime, and the Debate about Research Focus

The monumental age–crime debate in the early 80s served as growing pains for the subfield of developmental criminology (Hirschi and Gottfredson, 1983; Greenberg, 1985; Land, 1992; Warr, 1993). In 1983, Hirschi and Gottfredson wrote what served as an open letter to the research community on the trend toward investing increasing amounts of talent and fiscal resources on expensive longitudinal studies, which they argued were unnecessary to understanding the causes of crime.

Writing in reaction to criticism launched against control and other theories that failed to account for aging out and other longitudinal effects, Hirschi and Gottfredson wrote most directly in critique of Greenberg's (1977) theoretical analysis, where he proposed using a combination of strain and control theories to account for variation in criminal behavior, including that variation due to age. Hirschi and Gottfredson argued that theories that adequately differentiate between criminals and noncriminals do not have to account for the effects of age or the various dimensions of the criminal career. Crime, they maintain, can be explained by individual differences.

The typical curve, as depicted in the figure below showing the age of arrestees in detailed national crime reports (e.g., Federal Bureau of Investigation, 2012), can be described as a distinct peak in activity in the late teens, a sudden decline in early adulthood, and a continual decline as age increases. This pattern is consistent with the typical age–crime curve discussed in research literature (Gottfredson and Hirschi, 1988; Greenberg, 1985; Blumstein et al., 1988; Moffitt, 1993) from reports of the US crime rates and similar statistics from the British Home Office (Hansen, 2003). This age distribution, as Gottfredson and Hirschi argue based on similar graphs of crime rates from the United States, England, and Wales across several periods, e.g., 1840, 1908, 1965, and 1977, "is invariant across social and cultural conditions," as well as across genders (Steffensmeier et al., 2006; **Figure 1**).

Because it is ubiquitous, Hirschi and Gottfredson state that the age–crime distribution "cannot be accounted for by any variable or combination of variables currently available to criminology" (1983), as these variables are often confounded with age. In causation terms, they stated that the age effect on crime is direct. Given the primacy of self-control and the stability of between-person differences in self-control in their general theory, Gottfredson and Hirschi argued that explanations of crime at one age suffice to explain crime at any other. Self-control, moreover, is usually set by mid-childhood (8–10 years of age). There is 'stability,' they argued, in the different likelihood that individuals would commit crimes.

Greenberg (1985) demonstrated that the age–crime relationship is not universal but shows demographic

Figure 1 U.S. arrest rates by age. From Federal Bureau of Investigation, 2012. Crime in the United States.

variation and changes over historical periods. He cited several examples of socioeconomic status, gender, and race differences in the age distribution of crime, measured by arrests and survey responses from a variety of settings and locales. He also presented shifts in peak ages across time and evidence of social and demographic effects on desistance.

Warr (1993), responding to the statement that the age distribution of crime cannot be explained by any known variables (Hirschi and Gottfredson, 1983; Gottfredson and Hirschi, 1990), used National Youth Survey data to investigate how differential association theory can explain the age distribution. Exposure to delinquent peers, time spent with peers, and loyalty to peers changes dramatically from 11 to 21 years of age, following the same pattern as crime. Peers have more of an influence in early years, especially the teen years, than later in life. Moreover, the set of predictors of onset at early ages is somewhat different from the set that would predict onset at later ages, and these sets are different from the predictors of persistence in crime (Nagin and Farrington, 1992b).

More recently, Sweeten et al., (2013) demonstrated the relative importance of developmental and criminological concepts in explaining the reduction of criminal behavior over a 7-year period observed in the Pathways to Desistance study. The use of a multilevel model which allowed precise assessment of change in correlates such as psychosocial maturity and social control demonstrated that the effect of age on decrease in criminal behavior in their sample is not direct as argued by Gottfredson and Hirschi.

Developmental criminology, borrowing human development concepts from psychology and expanding on control theory, social learning, strain and symbolic interaction, enhances the notion of criminal career with time-dependent models of change in behavior (Farrington, 2003). Processes such as 'aging out' of crime (Gottfredson and Hirschi, 1986, 1990; Sampson and Laub, 2003) necessitate a longitudinal perspective and the assumption of the possibility of change.

Career Criminals and Population Heterogeneity

Age–crime curves for individuals do not resemble the aggregate curve (Farrington, 1986), and there is an extensive individual variation in the timing of onset, incidence, desistance, and the correlates of these trajectories. The earliest criminologists have noted that some members of the population commit more crimes than others (Lombroso, 2006). While the various crime indicators vary by age, researchers have argued that a certain small segment of the population is responsible for a large percentage of delinquent acts (Blumstein et al., 1985; Wolfgang et al., 1972). Wolfgang et al., (1972) found, in addition to large race and socio economic status (SES) differences in offending, severity, and repeat offending, that 6% of the sample was responsible for 52% of offenses.

Those who commit delinquent acts earlier in life tend to commit more crime later. These early-onset, (and potentially) chronic offenders are the subject of a large amount of research using cohort data sets (e.g., Blumstein et al., 1985). However, Blumstein et al., (1985) took special pains to disambiguate the concepts of *criminal career* and *career criminal*. The latter, they noted, was more sensational, resonating more with policy interests but not as theoretically interesting as the former.

Analyzing the Cambridge Study in Delinquency Development panel of data on 411 boys followed into manhood, Nagin and Farrington (1992a,b) found an inverse association between the age of onset and future conviction. Personal characteristics and family factors, such as the 'daring' nature of the boy, the criminal history and attitudes of his parents, and separation from parents, have some bearing on the boy's onset of criminal behavior and its continuation, lending credence to 'persistent heterogeneity theories' of behavioral change (Gottfredson and Hirschi, 1990; Wilson and Herrnstein, 1985).

The heterogeneity perspective on behavioral change resonates with some of the more classic debates on deviant careers. For instance, this debate was foreshadowed, according to Laub and Sampson (1991), by the debate between Sutherland and the Gluecks, who "sought to understand the age–crime curve in terms of maturational reform" as they investigated their hypothesis regarding the stability of deviance (Laub and Sampson, 1991: 1410), a 'sticking point' generating opposition from those tied to a more sociological perspective, such as Sutherland's differential association. The Glueck focus, in analyzing differences between delinquents and nondelinquents, was 'multidisciplinary' and took a 'multiple causal approach' but also intensely individual – investigating family and other microlevel factors such as "school, opportunities (peers and the use of leisure time), formal sanctions (e.g., arrest, probation, prison), personality development, temperament, and constitutional factors such as body structure (e.g., mesomorphy)" (Laub and Sampson, 1991).

By contrast, Sutherland took a more sociological position and objected to the Gluecks' multiple factor, individual level 'factual search,' devoid of a formal, articulated theory of persistent criminality (Laub and Sampson, 1991). The substantive contention between Sutherland and the Gluecks, as between Hirschi and Gottfredson and other scholars, stemmed from the fundamental relevance of age to crime, which Sutherland dismissed as "slightly more than chance" (quoted in Laub and Sampson, 1991: 1422), and the stability of antisocial behavior over the life course, which he denied.

Another contention was the Gluecks' practical ambition to "influence social policy through the use of their prediction tables"; to improve the process of decision-making by judges, probation officers, parole boards, and military officials; and to identify potential delinquents at school age or perhaps even as early as 2 or 3 years of age to "make possible the application of treatment measures that would be truly crime preventive" (1950, cited in Sampson and Laub, 1993). The Gluecks' ambitions have resonated in much of the applied social research, particularly contemporary study of serious offenders, chronic offenders, selective incapacitation, early intervention, and targeted crime prevention (Blumstein et al., 1985; Blumstein et al., 1988).

State Dependence/Persistence and Desistance

Modern longitudinal research has investigated the notion of state dependence, i.e., the temporal association between prior/current and future behavior (D'Unger et al., 1998;

Skardhamar, 2010). Conceptualized this way, prior offending is still an etiological factor, but the analytic focus is less on a particular age of onset and more focused on the timing of prior incidence. The issue here is one of persistence: current deviants are more likely to remain deviant in the near future, either because their circumstances or social networks are likely to remain the same or worse due to their behavior (Sampson and Laub, 1993), or because latent, time-stable antisocial traits make them more likely to persist (Gottfredson and Hirschi, 1990). Both explanations have implications for differences in short- and long-term trajectories.

Desistance, in another extension of the maturational reform perspective lent to the discipline by the Gluecks, is conceived as a socially nuanced and incremental process (Laub and Sampson, 2003; Bushway and Paternoster, 2013). Ezell and Cohen, in their book based on the analysis of arrest histories in a delinquent population identified by the California Youth Authority in 1981–82, 1986–87, and 1991–92, found some continuity of arrest patterns (state dependence) in shorter rather than longer periods of time. However, their findings included a surprisingly large amount of variation ('heterogeneity') in longer-term longitudinal patterns among delinquents, lending little support to theories of stability.

Laub and Sampson (2003), in a study unparalleled in depth, found continuity in antisocial behavior among delinquents followed over decades and observed via retrospective interviews. However, like others, they found extensive variation in the persistence of deviant and criminal behavior. Desistance, which Sampson and Laub show to be more common than the career criminal model would suggest, is related to social bonds (e.g., family and employment) and the informal social control these bonds generate. Adult attachments are associated with increased social resources, which are, in turn, associated with decreased antisocial behavior.

The acquisition of these social resources led to desistance from delinquent behavior but not certain deviant behavior such as alcohol abuse and violence. Important macrolevel structural factors such as the GI Bill played a part in the directions the interviewee's lives took. Thus, behavioral change over the life course is said to be influenced by "interaction of structure and choice" (2003).

The Sampson and Laub study was not of the same magnitude as the Ezell and Cohen and other large longitudinal studies (e.g., Wolfgang et al., 1987; Bushway et al., 2009) emerging from a delinquent population, or Farrington and West (Farrington et al., 2006), emerging from a general population. However, no longitudinal study has achieved the depth of the Laub and Sampson study in investigating underlying processes in delinquent and deviant behavior over the life course.

Based on evidence of various types (survey research, longitudinal designs, criminal histories, or narrative studies), desistance is shown to be the norm for most offenders (Sampson and Laub, 2005b; Maruna, 1999; Massoglia and Uggen, 2010).

Behavioral Trajectories and Group-Based Analysis

Due to technological and methodological advances in research subject tracking and longitudinal data collection, the longitudinal study of crime has reached paradigmatic status. Following the Gluecks, the research of Wolfgang and others working on the Philadelphia birth cohort reflected a lasting interest in chronic offenders and the debate over what distinguishes chronic offenders. This interest developed into research questions such as whether chronic offenders are a separate type of person, with separate causes for their behavior and a set of characteristics that can be used to identify them.

Moffitt (1993) proposed the existence of two behavioral groups, defined as "qualitatively distinct categories of individuals … each in need of its own distinct theoretical explanation" (Moffitt, 1993: 674). The first of these groups consists of those offenders who temporarily participate in delinquent acts, usually in the teen years, and promptly desist. The second group persists with delinquency throughout the life course. This proposition represented a major advance in the rapidly developing subfield of developmental criminology (Loeber and Le Blanc, 1990; Laub and Sampson, 1993; Nagin and Farrington, 1992a,b), and it subsequently influenced well over 200 articles in sociology, psychology, education, criminology, political science, and criminal justice.

Nagin and Land (1993) made an equally important impact by presenting statistical models that depict population heterogeneity in behavioral trajectories. In their widely read paper, they argued that such heterogeneity can be estimated with mutually exclusive groups based on the observed data. Generally, these models are estimated with an algorithm that 'searches' a longitudinal data set (Moffitt, 2006), posits a user-supplied number of trajectory groups, and then assigns a probability of membership in each group to each case. Analysts can also estimate the proportion of the population in each group.

With the development of group-based modeling procedures in popular statistical software (Jones et al., 2001; Deb, 2008; Muthén, 2004), a growing body of research has emerged using these techniques and a variety of behavioral data (Roeder et al., 1999; Jones et al., 2001; Piquero et al., 2007). A hypothetical set of trajectories, including those proposed by Moffitt, are depicted in the figure below (**Figure 2**).

The key innovation with these methods is the ability to describe "not just the average path but the full distribution of individual trajectories" (Bushway et al., 2009). Thus, a modern feature of longitudinal study is the examination of trajectories – onset, peak, and desistance – as whole units rather than separate dimensions. But the discoveries here were not just methodological; trajectory group presented a new agenda for sociological theory (D'Unger et al., 1998).

Some controversy has followed the group-based trajectory methods. Piquero (2008), who reviewed over 80 studies using group-based trajectory, noted that the source of sample, i.e., offenders versus general population, the length of the observation, and other methodological choices make a difference in the number of groups. In fact, group membership is unstable, especially among 'high-rate chronic' offenders, and highly sensitive to the inclusion of incarceration time (Eggleston et al., 2004). Bauer and Curran (2003) noted a higher risk of falsely inferring groups when using these methods on skewed data.

Group-based discussion, particularly the use of strongly intuitive labels such as 'adolescent limiteds,' 'high-level chronics,' and 'low-level chronics' (Nagin and Land, 1993;

Figure 2 Example of four behavioral trajectories, ages 10 through 70.

Nagin et al., 1995), risks "misappropriation by those predisposed to believe in the idea of a high-rate group" (Sampson and Laub, 2005a, paraphrased by Piquero, 2008). Once groups are 'identified' with statistical models, researchers are inclined to discuss them as *actual groups*, often in the sense that scientists speak of 'natural categories' existing in nature (Skardhamar, 2010). Thus, the policy implications of group-based analysis, particularly the potential for targeting crime prevention and intervention resources (D'Unger et al., 1998; Sampson and Laub, 2005a; Nagin, 2005), are more negative than positive.

Much of the contention around group-based methods questions the assumption of discrete groups. Simulation studies based on artificial data with and without groups (Greenberg and Ezell, 2011; Bauer and Curran, 2003; Skardhamar, 2010) have demonstrated the possibility of finding groups where there were none.

Thus, as Raudenbush (2005) suggested when he wrote, "perhaps we are better off assuming continuously varied growth a priori and therefore never tempting our audience," some recent research has been done with this more relaxed assumption (Telesca et al., 2012; Greenberg and Ezell, 2011; Phenix, 2010). Using visual representation and statistical tests on the distribution of estimated parameters (intercepts and slopes) from multilevel models, these studies estimated the whole population of trajectories in a 19-year panel data of delinquent men (Greenberg and Ezell, 2011) and a 40-year cohort study of men from a general population (Phenix, 2010). Testing the assumption of trajectory groups by first examining the continuum of criminal behavior trajectories, these studies found no strong evidence of trajectory groups. Telesca et al., (2012) also demonstrated the use and importance of more flexible models of deviant behavior based on data from a general population.

All of the studies on behavioral trajectories demonstrate that change over the life course is not universal. However, the variation in how, how much, and when the behavior changes is of continued interest to social scientists. In sum, the shape of the distribution of deviant behavior – and of change in that behavior – is a fundamental question of long-term interest in criminology (Glueck and Glueck, 1940; Sampson and Laub, 1993, 2003; Moffitt, 2003). In investigating how change or the absence of change is connected to and influenced by the social context and the functioning of social institutions at both individual and structural levels, the study of age as related to crime remains an important lens for connecting human behavior and the age-graded set of expectations, resources, and challenges faced by people and the society that they comprise.
